(54) Title: TRANSCRIPTION FACTOR STRESS-RELATED PROTEINS AND METHODS OF USE IN PLANTS

**Wild Type**

**PpHDZ-1**

(57) Abstract: A transgenic plant transformed by a transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein expression of the nucleic acid sequence in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant. Also provided are agricultural products, including seeds, produced by the transgenic plants. Also provided are isolated TFSRP, and isolated nucleic acid coding TFSRP, and vectors and host cells containing the latter. Further provided are methods of producing transgenic plants expressing TFSRP, methods of increasing expression of other genes of interest using the TFSRP, methods of identifying novel TFSRP, and methods of modifying the expression of TFSRP in plants.

## TRANSCRIPTION FACTOR STRESS-RELATED PROTEINS AND METHODS OF USE IN PLANTS

15

### BACKGROUND OF THE INVENTION

#### Field of the Invention

20

This invention relates generally to nucleic acid sequences encoding proteins that are associated with abiotic stress responses and abiotic stress tolerance in plants. In particular, this invention relates to nucleic acid sequences encoding proteins that confer drought, cold, and/or salt tolerance to plants.

#### Background Art

25

Abiotic environmental stresses, such as drought stress, salinity stress, heat stress, and cold stress, are major limiting factors of plant growth and productivity. Crop losses and crop yield losses of major crops such as rice, maize (corn) and wheat caused by these stresses represent a significant economic and political factor and contribute to food shortages in many underdeveloped countries.

30

Plants are typically exposed during their life cycle to conditions of reduced environmental water content. Most plants have evolved strategies to protect themselves against these conditions of desiccation. However, if the severity and duration of the drought conditions are too great, the effects on plant development, growth and yield of most crop plants are profound. Furthermore, most of the crop plants are very susceptible to higher salt concentrations in the soil. Continuous exposure to drought and high salt causes major alterations in the plant metabolism. These great changes in metabolism ultimately lead to cell death and consequently yield losses.

35

Developing stress-tolerant plants is a strategy that has the potential to solve or mediate at least some of these problems. However, traditional plant breeding strategies to develop new lines of plants that exhibit resistance (tolerance) to these types of stresses are relatively slow and require specific resistant lines for crossing with the desired line. Limited germplasm resources for stress tolerance and incompatibility in crosses between distantly related plant species represent significant problems encountered in conventional breeding. Additionally, the cellular processes leading to drought, cold and salt tolerance in model, drought- and/or salt-tolerant plants are complex in nature and involve multiple mechanisms of cellular adaptation and numerous metabolic pathways. This multi-component nature of stress tolerance has not only made breeding for tolerance largely unsuccessful, but has also limited the ability to genetically engineer stress tolerance plants using biotechnological methods.

Therefore, what is needed is the identification of the genes and proteins involved in these multi-component processes leading to stress tolerance. Elucidating the function of genes expressed in stress tolerant plants will not only advance our understanding of plant adaptation and tolerance to environmental stresses, but also may provide important information for designing new strategies for crop improvement.

One model plant used in the study of stress tolerance is *Arabidopsis thaliana*. There are at least four different signal-transduction pathways leading to stress tolerance in the model plant *Arabidopsis thaliana*. These pathways are under the control of distinct transcription factors (Shinozaki et al., 2000 Curr. Op. Pl. Biol. 3:217-23). Regulators of genes, especially transcription factors, involved in these tolerance pathways are particularly suitable for engineering tolerance into plants because a single gene can activate a whole cascade of genes leading to the tolerant phenotype. Consequently, transcription factors are important targets in the quest to identify genes conferring stress tolerance to plants.

One transcription factor that has been identified in the prior art is the *Arabidopsis thaliana* transcription factor CBF (Jaglo-Ottosen et al., 1998 Science 280:104-6). Over-expression of this gene in *Arabidopsis* conferred drought tolerance to this plant (Kasuga et al., 1999 Nature Biotech. 17:287-91). However, CBF is the only example to date of a transcription factor able to confer drought tolerance to plants upon over-expression.

Although some genes that are involved in stress responses in plants have been characterized, the characterization and cloning of plant genes that confer stress tolerance remains largely incomplete and fragmented. For example, certain studies have indicated that drought and salt stress in some plants may be due to additive gene effects, in contrast to other research that indicates specific genes are transcriptionally

activated which leads to accumulation of new proteins in vegetative tissue of plants under osmotic stress conditions. Although it is generally assumed that stress-induced proteins have a role in tolerance, direct evidence is still lacking, and the functions of many stress-responsive genes are unknown.

There is a need, therefore, to identify genes expressed in stress tolerant plants that have the capacity to confer stress resistance to its host plant and to other plant species. Newly generated stress tolerant plants will have many advantages, such as increasing the range that crop plants can be cultivated by, for example, decreasing the water requirements of a plant species.

## SUMMARY OF THE INVENTION

This invention fulfills in part the need to identify new, unique transcription factors capable of conferring stress tolerance to plants upon over-expression. Namely, described herein are the transcription factors: 1) CAAT-Box like Binding Factor-1 (CABF-1); 2) CABF-2 3) DNA Binding Factor-1 (DBF-1); 4) CRT/DRE Binding Factor (CBF-1); 5) Homeo Domain/Leucine Zipper (HDZ-1); 6) Zinc-Finger Factor (ZF-1) and 7) Leucine Zipper (LZ-1), all from *Physcomitrella patens*.

The present invention provides a transgenic plant transformed by a transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein expression of the nucleic acid sequence in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant. The invention provides that the TFSRP can be selected from one of the well known general classes of transcription factor proteins: 1) CAAT-Box like Binding Factor (CABF); 2) DNA Binding Factor (DBF); 3) Homeo Domain/Leucine Zipper (HDZ); 4) Zinc-Finger Factor (ZF); and 5) Leucine Zipper (LZ). The invention further provides specific examples of TFSRPs, and TFSRP coding nucleic acids, such as 1) CABF-1; 2) CABF-2; 3) DBF-1; 4) CRT/DRE Binding Factor (CBF-1); 5) HDZ-1; 6) ZF-1 and 7) LZ-1.

The invention provides in some embodiments that the TFSRP and coding nucleic acid are that found in members of the genus *Physcomitrella*. In another preferred embodiment, the nucleic acid and protein are from a *Physcomitrella patens* plant. The invention provides that the environmental stress can be salinity, drought, temperature, metal, chemical, pathogenic and oxidative stresses, or combinations thereof. In preferred embodiments, the environmental stress can be salinity, drought, and temperature, or combinations thereof.

The invention further provides a seed produced by a transgenic plant transformed by a TFSRP coding nucleic acid, wherein the plant is true breeding for increased tolerance to environmental stress as compared to a wild type variety of the

plant. The invention further provides a seed produced by a transgenic plant expressing a TFSRP, wherein the plant is true breeding for increased tolerance to environmental stress as compared to a wild type variety of the plant.

5 The invention further provides an agricultural product produced by any of the above-described transgenic plants. The invention further provides an isolated TFSRP, wherein the TFSRP is as described below. The invention further provides an isolated TFSRP coding nucleic acid, wherein the TFSRP coding nucleic acid codes for a TFSRP as described below.

10 The invention further provides an isolated recombinant expression vector comprising a TFSRP coding nucleic acid as described below, wherein expression of the vector in a host cell results in increased tolerance to environmental stress as compared to a wild type variety of the host cell. The invention further provides a host cell containing the vector and a plant containing the host cell.

15 The invention further provides a method of producing a transgenic plant with a TFSRP coding nucleic acid, wherein expression of the nucleic acid in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant comprising: (a) transforming a plant cell with an expression vector comprising a TFSRP coding nucleic acid, and (b) generating from the plant cell a transgenic plant with an increased tolerance to environmental stress as compared to a wild type variety  
20 of the plant. In preferred embodiments, the TFSRP is as described below. In preferred embodiments, the TFSRP coding nucleic acid is as described below.

The invention further provides a method of increasing expression of a gene of interest within a host cell as compared to a wild type variety of the host cell, wherein the gene of interest is transcribed in response to a TFSRP, comprising: (a) transforming  
25 the host cell with an expression vector comprising a TFSRP coding nucleic acid, and (b) expressing the TFSRP within the host cell, thereby increasing the expression of the gene transcribed in response to the TFSRP as compared to a wild type variety of the host cell. In preferred embodiments, the TFSRP is as described below. In preferred embodiments, the TFSRP coding nucleic acid is as described below.

30 The present invention further provides a method of identifying a novel TFSRP, comprising (a) raising a specific antibody response to a TFSRP, or fragment thereof, as described above; (b) screening putative TFSRP material with the antibody, wherein specific binding of the antibody to the material indicates the presence of a potentially novel TFSRP; and (c) analyzing the bound material in comparison to known TFSRP to  
35 determine its novelty.

## BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1(A-G) show the partial cDNA sequences of CABF-1 (SEQ ID NO:1), DBF-1 (SEQ ID NO:2), CBF-1 (SEQ ID NO:3), HDZ-1 (SEQ ID NO:4), ZF-1 (SEQ ID NO:5), LZ-1 (SEQ ID NO:6) and CABF-2 (SEQ ID NO:7) from *Physcomitrella patens*.

Figures 2(A-H) show the full-length cDNA sequences of CABF-1 (SEQ ID NO:8), DBF-1 (SEQ ID NO:9), DBF-1 variant (SEQ ID NO:22), CBF-1 (SEQ ID NO:10), HDZ-1 (SEQ ID NO:11), ZF-1 (SEQ ID NO:12), LZ-1 (SEQ ID NO:13) and CABF-2 (SEQ ID NO:14) from *Physcomitrella patens*.

Figures 3(A-H) show the deduced amino acid sequences of CABF-1 (SEQ ID NO:15), DBF-1 (SEQ ID NO:16), DBF-1 variant (SEQ ID NO:23), CBF-1 (SEQ ID NO:17), HDZ-1 (SEQ ID NO:18), ZF-1 2 (SEQ ID NO:19), LZ-1 (SEQ ID NO:20) and CABF-2 (SEQ ID NO: 21) from *Physcomitrella patens*.

Figure 4 shows a diagram of the plant expression vector pGMSG containing the super promoter driving the expression of SEQ ID NOs: 8, 9, 10, 11, 12, 13, and 14 ("Desired Gene"). The components are: aacCI gentamycin resistance gene (Hajdukiewicz et al., 1994 Plant Molecular Biology 25:989-94), NOS promoter (Becker et al., 1992 Plant Molecular Biology 20:1195-7), gTT terminator (Becker et al., 1992), NOSpA terminator (Jefferson et al., 1987 EMBO J. 6:3901-7).

Figure 5 shows the results of a drought stress test with over-expressing HDZ-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 6 shows the results of a drought stress test with over-expressing ZF-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 7 shows the results of a drought stress test with over-expressing CABF-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 8 shows the results of a drought stress test with over-expressing DBF-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 9 shows the results of a drought stress test with over-expressing CABF-2 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 10 shows the results of a drought stress test with over-expressing LZ-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 11 shows the results of a drought stress test with over-expressing CBF-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 12 shows the results of a salt stress test with over-expressing ZF-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 13 shows the results of a salt stress test with over-expressing CABF-2 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

Figure 14 shows the results of a salt stress test with over-expressing LZ-1 from *Physcomitrella patens* in transgenic plants and wild-type *Arabidopsis* lines. The transgenic lines display a tolerant phenotype. Individual transformant lines are shown.

#### DETAILED DESCRIPTION OF THE INVENTION

The present invention may be understood more readily by reference to the following detailed description of the preferred embodiments of the invention and the Examples included herein. However, before the present compounds, compositions, and methods are disclosed and described, it is to be understood that this invention is not limited to specific nucleic acids, specific polypeptides, specific cell types, specific host cells, specific conditions, or specific methods, etc., as such may, of course, vary, and the numerous modifications and variations therein will be apparent to those skilled in the art. It is also to be understood that the terminology used herein is for the purpose of describing specific embodiments only and is not intended to be limiting. In particular, the designation of the amino acid sequences as "Transcription Factor Stress-related Proteins" (TFSRPs), in no way limits the functionality of those sequences.

The present invention provides a transgenic plant transformed by a TFSRP coding nucleic acid, wherein expression of the nucleic acid sequence in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant. The invention further provides a seed produced by a transgenic plant transformed by a TFSRP coding nucleic acid, wherein the seed contains the TFSRP coding nucleic acid, and wherein the plant is true breeding for increased tolerance to environmental stress as compared to a wild type variety of the plant. The

invention further provides a seed produced by a transgenic plant expressing a TFSRP, wherein the seed contains the TFSRP, and wherein the plant is true breeding for increased tolerance to environmental stress as compared to a wild type variety of the plant. The invention further provides an agricultural product produced by any of the above-or below-described transgenic plants. As used herein, the term "variety" refers to a group of plants within a species that share constant characters that separate them from the typical form and from other possible varieties within that species. While possessing at least one distinctive trait, a variety is also characterized by some variation between individuals within the variety, based primarily on the Mendelian segregation of traits among the progeny of succeeding generations. A variety is considered "true breeding" for a particular trait if it is genetically homozygous for that trait to the extent that, when the true-breeding variety is self-pollinated, a significant amount of independent segregation of the trait among the progeny is not observed. In the present invention, the trait arises from the transgenic expression of a single DNA sequence introduced into a plant variety.

The invention further provides an isolated TFSRP. The invention provides that the TFSRP can be selected from one of the well known general classes of transcription factor proteins, such as: 1) CAAT-Box like Binding Factor (CABF); 2) DNA Binding Factor (DBF); 3) Homeo Domain/Leucine Zipper (HDZ); 4) Zinc-Finger Factor (ZF); and 5) Leucine Zipper (LZ). It is a novel finding of the present invention that these classes of transcription factors are involved in stress tolerance in plants and that expression of a member of one of these protein classes in a plant can increase that plant's tolerance to stress. In further preferred embodiments, the TFSRP is selected from 1) a CAAT-Box like Binding Factor-1 (CABF-1) as defined in SEQ ID NO:15; 2) a CABF-2 as defined in SEQ ID NO:21; 3) a DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:16; 4) a CRT/DRE Binding Factor (CBF-1) as defined in SEQ ID NO:17; 5) a Homeo Domain/Leucine Zipper (HDZ-1) as defined in SEQ ID NO:18; 6) a Zinc-Finger Factor (ZF-1) as defined in SEQ ID NO:19; 7) a Leucine Zipper (LZ-1) as defined in SEQ ID NO:20; 8) a DNA Binding Factor-1 variant (DBF-1v) as defined in SEQ ID NO:23 and homologues thereof. Homologues of the amino acid sequences are defined below.

The invention further provides an isolated TFSRP coding nucleic acid. The present invention includes TFSRP coding nucleic acids that encode TFSRPs as

described herein. In preferred embodiments, the TFSRP coding nucleic acid is selected from 1) a CAAT-Box like Binding Factor-1 (CABF-1) as defined in SEQ ID NO:1; 2) a CABF-2 as defined in SEQ ID NO:7; 3) a DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:2; 4) a CRT/DRE Binding Factor (CBF-1) as defined in SEQ ID NO:3; 5) a Homeo Domain/Leucine Zipper (HDZ-1) as defined in SEQ ID NO:4; 6) a Zinc-Finger Factor (ZF-1) as defined in SEQ ID NO:5; 7) a Leucine Zipper (LZ-1) as defined in SEQ ID NO:6; a DNA Binding Factor-1 variant (DBF-1v) as defined in SEQ ID NO:22 and homologues thereof. Homologues of the nucleotide sequences are defined below. In one preferred embodiment, the nucleic acid and protein are isolated from the plant genus *Physcomitrella*. In another preferred embodiment, the nucleic acid and protein are from a *Physcomitrella patens* (*P. patens*) plant.

As used herein, the term "environmental stress" refers to any sub-optimal growing condition and includes, but is not limited to, sub-optimal conditions associated with salinity, drought, temperature, metal, chemical, pathogenic and oxidative stresses, or combinations thereof. In preferred embodiments, the environmental stress can be salinity, drought, and temperature, or combinations thereof, and in particular, can be high salinity, low water content and low temperature. It is also to be understood that as used in the specification and in the claims, "a" or "an" can mean one or more, depending upon the context in which it is used. Thus, for example, reference to "a cell" can mean that at least one cell can be utilized.

In accordance with the purposes of this invention, as embodied and broadly described herein, this invention, in one aspect, provides an isolated nucleic acid from a moss encoding a Stress-related Protein (SRP), or a portion thereof. In particular, the present invention provides nucleic acids encoding TFSRPs including the nucleic acid sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 and SEQ ID NO:22. The present invention also provides amino acid sequences of TFSRPs including the amino acid sequences shown in SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 and SEQ ID NO:23.

The present invention describes for the first time the predicted *P. patens* proteins CABF-1 (SEQ ID NO:15) and CABF-2 (SEQ ID NO:21) that are homologous to CAAT-Box Binding Factors. (Homology to other proteins is shown in Tables 4 and 6, respectively). The amino acid sequence of CABF-1 (SEQ ID NO:15) is similar to

the domain "B" of other CAAT-Box Binding Factors (Johnson and McKnight, 1989 Ann. Rev. Biochem. 58:799-840). In general, CABFs are members of multi-component transcription activation complex. They are involved as general transcriptional regulators as well as in the activation of specific genes. The particular combination of the different CABFs and other sub-units determines which genes are targeted and activated. The present invention also describes for the first time that CABF proteins such as CABF-1 (SEQ ID NO:15), are useful for increasing stress tolerance in plants. Particularly, the present invention demonstrates that CABF-1 is important for the activation of drought-related genes upon expression in *Arabidopsis thaliana*.

Another novel predicted *P. patens* protein described herein is DBF-1 (SEQ ID NO:16), which is homologous to several eukaryotic proteins implicated in gene regulation (transcription factors) and/or chromatin structure modulation (i.e. helicases), for example the gene Etl-1 from mouse (Soininen et al. 1992 Mech Dev. 39:111-23). (Homology to other proteins is shown in Table 5). The identity between DBF-1 (SEQ ID NO:16) and Etl-1 is greater in the C-terminus of the later; a region where the identity with other known transcription factors and/or helicases (chromatin-structure changing proteins) is the greatest. Hence, DBF-1 (SEQ ID NO:16) contains the functional domains of these other proteins, a fact that strengthens the hypothesis that this protein functions *in vivo*. Over-expression of DBF-1 in *Arabidopsis thaliana* permits for the constitutive, strong expression of drought-related genes in this plant, and results in a drought tolerant plant. Interestingly, there seem to be two specifically observed variant forms of protein DBF-1, SEQ ID NO:16 and SEQ ID NO:23, in *P. patens* and both variants are equally efficient in conferring stress tolerance to a transgenic plant.

Another novel predicted *P. patens* protein described herein is CBF-1 (SEQ ID NO:17), which is a homologue of the *Arabidopsis thaliana* transcription factor CBF-1. (Homology to other proteins is shown in Table 8). As mentioned before, expression of CBF-1 leads to stress-tolerant plants. Because CBF-1 (SEQ ID NO:17) originates from a stress-tolerant plant, *Physcomitrella patens*, it is conceivable that this gene confers a higher level of stress tolerance to other plants than the *Arabidopsis* homologue.

Yet another discovery of the present invention is that a group of Homeodomain/Leucine Zipper transcription factors confer increased stress tolerance to

plants. Also described is a novel predicted *P. patens* protein designated HDZ-1 (SEQ ID NO:18), which is a homologue of HD-Z transcription factors found in plants. (Homology to other proteins is shown in Table 2). Homeodomain (HD) transcription factors have been well characterized in animals as being involved in organ formation.

5 In plants, HD proteins seem to contain, in many cases, an adjacent Leucine Zipper domain (HD-Z proteins). Most of these genes are specifically expressed in meristems; consistent with their role in morphology determination (Tornero et al., 1996 Pl. J. 9:639-48). However, HD-Z proteins have also been implicated in non-developmental processes. Expression of HDZ-1 (SEQ ID NO:18) in *Arabidopsis thaliana*

10 constitutively activates genes involved in drought tolerance, resulting in drought-tolerant plants.

Another novel predicted *P. patens* protein described herein is ZF-1 (SEQ ID NO:19), which shows sequence similarity to the Zinc-Finger class of transcription factors. (Homology to other proteins is shown in Table 3). Zinc-finger transcription

15 factors share a specific secondary structure where a zinc molecule is sequestered via its interaction with cysteine or histidine amino acid residues. Through these "fingers," the proteins interact with their specific DNA targets. After binding, they regulate transcription of the target genes. Zinc-finger factors are associated in yeast with the regulation of multiple genes, e.g., genes involved in general metabolism. In plants, a

20 zinc-finger protein, CONSTANS, is responsible for determining flowering time (Putterill et al., 1995 Cell 80:847-57). The present invention also describes for the first time that ZF transcription factors are useful for increasing stress tolerance in plants. Particularly, the present invention demonstrates that ZF-1 from *P. patens* is important for the activation of drought-related genes upon expression in *Arabidopsis thaliana*.

25 Another novel predicted protein described herein is LZ-1 (SEQ ID NO:20), which shares amino acid sequence similarity with other Leucine-Zipper transcription factors (Ehrlich et al., 1992 Gene 15: 169-78). (Homology to other proteins is shown in Table 7). Leucine-Zipper transcription factors are also involved in numerous other processes in the life cycle of a plant; ranging from light-specific gene expression to

30 seed-specific gene induction. The present invention described for the first time that LZ transcription factors confer stress tolerance to transgenic plants, and in particular that LZ-1 from *P. patens* confers stress tolerance to *Arabidopsis thaliana* plants.

One aspect of the invention pertains to isolated nucleic acid molecules that encode TFSRP polypeptides or biologically active portions thereof, as well as nucleic acid fragments sufficient for use as hybridization probes or primers for the identification or amplification of TFSRP-encoding nucleic acid (e.g., TFSRP DNA).

As used herein, the term "nucleic acid molecule" is intended to include DNA molecules (e.g., cDNA or genomic DNA) and RNA molecules (e.g., mRNA) and analogs of the DNA or RNA generated using nucleotide analogs. This term also encompasses untranslated sequence located at both the 3' and 5' ends of the coding region of the gene: at least about 1000 nucleotides of sequence upstream from the 5' end of the coding region and at least about 200 nucleotides of sequence downstream from the 3' end of the coding region of the gene. The nucleic acid molecule can be single-stranded or double-stranded, but preferably is double-stranded DNA. An "isolated" nucleic acid molecule is one that is substantially separated from other nucleic acid molecules which are present in the natural source of the nucleic acid. Preferably, an "isolated" nucleic acid is free of some of the sequences which naturally flank the nucleic acid (i.e., sequences located at the 5' and 3' ends of the nucleic acid) in the genomic DNA of the organism from which the nucleic acid is derived. For example, in various embodiments, the isolated TFSRP nucleic acid molecule can contain less than about 5 kb, 4 kb, 3 kb, 2 kb, 1 kb, 0.5 kb or 0.1 kb of nucleotide sequences which naturally flank the nucleic acid molecule in genomic DNA of the cell from which the nucleic acid is derived (e.g., a *Physcomitrella patens* cell). Moreover, an "isolated" nucleic acid molecule, such as a cDNA molecule, can be free from some of the other cellular material with which it is naturally associated, or culture medium when produced by recombinant techniques, or chemical precursors or other chemicals when chemically synthesized.

A nucleic acid molecule of the present invention, e.g., a nucleic acid molecule having a nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, or a portion thereof, can be isolated using standard molecular biology techniques and the sequence information provided herein. For example, a *P. patens* TFSRP cDNA can be isolated from a *P. patens* library using all or portion of one of the sequences of SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, and SEQ ID NO:7 as a hybridization probe and standard hybridization techniques (e.g., as

described in Sambrook et al., 1989 *Molecular Cloning: A Laboratory Manual*, 2nd, ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). Moreover, a nucleic acid molecule encompassing all or a portion of one of the sequences of SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, and SEQ ID NO:7 can be isolated by the polymerase chain reaction using oligonucleotide primers designed based upon this sequence (e.g., a nucleic acid molecule encompassing all or a portion of one of the sequences of SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, and SEQ ID NO:7 can be isolated by the polymerase chain reaction using oligonucleotide primers designed based upon this same sequence of SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6, or SEQ ID NO:7). For example, mRNA can be isolated from plant cells (e.g., by the guanidinium-thiocyanate extraction procedure of Chirgwin et al., 1979 *Biochemistry* 18:5294-5299) and cDNA can be prepared using reverse transcriptase (e.g., Moloney MLV reverse transcriptase, available from Gibco/BRL, Bethesda, MD; or AMV reverse transcriptase, available from Seikagaku America, Inc., St. Petersburg, FL). Synthetic oligonucleotide primers for polymerase chain reaction amplification can be designed based upon one of the nucleotide sequences shown in SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:5, SEQ ID NO:6 or SEQ ID NO:7. A nucleic acid molecule of the invention can be amplified using cDNA or, alternatively, genomic DNA, as a template and appropriate oligonucleotide primers according to standard PCR amplification techniques. The nucleic acid molecule so amplified can be cloned into an appropriate vector and characterized by DNA sequence analysis. Furthermore, oligonucleotides corresponding to a TFSRP nucleotide sequence can be prepared by standard synthetic techniques, e.g., using an automated DNA synthesizer.

In a preferred embodiment, an isolated nucleic acid molecule of the invention comprises one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22. The sequences of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 correspond to the *Physcomitrella patens* TFSRP cDNAs of the invention. These cDNAs comprise sequences encoding TFSRPs (i.e., the "coding region", indicated in

Table 1), as well as 5' untranslated sequences and 3' untranslated sequences. It is to be understood that SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 comprise both coding regions and 5' and 3' untranslated regions. Alternatively, the nucleic acid molecule can comprise only the coding region of any of the sequences in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 or can contain whole genomic fragments isolated from genomic DNA. A coding region of these sequences is indicated as "ORF position". It is to be understood that the

In another preferred embodiment, an isolated nucleic acid molecule of the invention comprises a nucleic acid molecule which is a complement of one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, or a portion thereof. A nucleic acid molecule which is complementary to one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 is one which is sufficiently complementary to one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 such that it can hybridize to one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, thereby forming a stable duplex.

In still another preferred embodiment, an isolated nucleic acid molecule of the invention comprises a nucleotide sequence which is at least about 50-60%, preferably at least about 60-70%, more preferably at least about 70-80%, 80-90%, or 90-95%, and even more preferably at least about 95%, 96%, 97%, 98%, 99% or more homologous to a nucleotide sequence shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, or a portion thereof. In an additional preferred embodiment, an isolated nucleic acid molecule of the invention comprises a nucleotide sequence which hybridizes, e.g., hybridizes under stringent conditions, to one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, or a portion thereof. These

hybridization conditions include washing with a solution having a salt concentration of about 0.02 molar at pH 7 at about 60°C.

Moreover, the nucleic acid molecule of the invention can comprise only a portion of the coding region of one of the sequences in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 and SEQ ID NO:22, for example a fragment which can be used as a probe or primer or a fragment encoding a biologically active portion of a TFSRP. The nucleotide sequences determined from the cloning of the TFSRP genes from *P. patens* allows for the generation of probes and primers designed for use in identifying and/or cloning TFSRP homologues in other cell types and organisms, as well as TFSRP homologues from other mosses or related species. Therefore this invention also provides compounds comprising the nucleic acid molecules disclosed herein, or fragments thereof. These compounds include the nucleic acid molecules attached to a moiety. These moieties include, but are not limited to, detection moieties, hybridization moieties, purification moieties, delivery moieties, reaction moieties, binding moieties, and the like. The probe/primer typically comprises substantially isolated oligonucleotide. The oligonucleotide typically comprises a region of nucleotide sequence that hybridizes under stringent conditions to at least about 12, preferably about 25, more preferably about 40, 50 or 75 consecutive nucleotides of a sense strand of one of the sequences set forth in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 and SEQ ID NO:22, an anti-sense sequence of one of the sequences set forth in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 and SEQ ID NO:22, or naturally occurring mutants thereof. Primers based on a nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 can be used in PCR reactions to clone TFSRP homologues. Probes based on the TFSRP nucleotide sequences can be used to detect transcripts or genomic sequences encoding the same or homologous proteins. In preferred embodiments, the probe further comprises a label group attached thereto, e.g. the label group can be a radioisotope, a fluorescent compound, an enzyme, or an enzyme co-factor. Such probes can be used as a part of a genomic marker test kit for identifying cells which express an TFSRP, such as by measuring a level of a TFSRP-

encoding nucleic acid in a sample of cells, e.g., detecting TFSRP mRNA levels or determining whether a genomic TFSRP gene has been mutated or deleted.

In particular, a useful method to ascertain the level of transcription of the gene (an indicator of the amount of mRNA available for translation to the gene product) is to perform a Northern blot (for reference see, for example, Ausubel et al., 1988 Current Protocols in Molecular Biology, Wiley: New York), in which a primer designed to bind to the gene of interest is labeled with a detectable tag (usually radioactive or chemiluminescent), such that when the total RNA of a culture of the organism is extracted, run on gel, transferred to a stable matrix and incubated with this probe, the binding and quantity of binding of the probe indicates the presence and also the quantity of mRNA for this gene. This information at least partially demonstrates the degree of transcription of the transformed gene. Total cellular RNA can be prepared from cells, tissues or organs by several methods, all well-known in the art, such as that described in Bormann, E.R. et al., 1992 Mol. Microbiol. 6:317-326.

To assess the presence or relative quantity of protein translated from this mRNA, standard techniques, such as a Western blot, may be employed (see, for example, Ausubel et al., 1988 Current Protocols in Molecular Biology, Wiley: New York). In this process, total cellular proteins are extracted, separated by gel electrophoresis, transferred to a matrix such as nitrocellulose, and incubated with a probe, such as an antibody, which specifically binds to the desired protein. This probe is generally tagged with a chemiluminescent or colorimetric label that may be readily detected. The presence and quantity of label observed indicates the presence and quantity of the desired mutant protein present in the cell.

In one embodiment, the nucleic acid molecule of the invention encodes a protein or portion thereof which includes an amino acid sequence which is sufficiently homologous to an amino acid sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 such that the protein or portion thereof maintains the same or a similar function as the amino acid sequence to which it is compared. As used herein, the language "sufficiently homologous" refers to proteins or portions thereof which have amino acid sequences which include a minimum number of identical or equivalent (e.g., an amino acid residue which has a similar side chain as an amino acid residue in one of the ORFs of a sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID

NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23) amino acid residues to a TFSRP amino acid sequence such that the protein or portion thereof is able to participate in a stress tolerance response in a plant, or more particularly can participate in the transcription of a protein involved in a stress tolerance response in a *Physcomitrella patens* plant. Examples of such activities are also described herein. Examples of TFSRP activities are set forth in Table 1.

In another embodiment, the protein is at least about 50-60%, preferably at least about 60-70%, and more preferably at least about 70-80%, 80-90%, 90-95%, and most preferably at least about 96%, 97%, 98%, 99% or more homologous to an entire amino acid sequence shown in SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23. In yet another embodiment, at least about 50-60%, preferably at least about 60-70%, and more preferably at least about 70-80%, 80-90%, 90-95%, and most preferably at least about 96%, 97%, 98%, 99% or more homologous to an entire amino acid sequence encoded by a nucleic acid sequence shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22.

Portions of proteins encoded by the TFSRP nucleic acid molecules of the invention are preferably biologically active portions of one of the TFSRPs. As used herein, the term "biologically active portion of a TFSRP" is intended to include a portion, e.g., a domain/motif, of a TFSRP that participates in a stress tolerance response in a plant, or more particularly participates in the transcription of a protein involved in a stress tolerance response in a plant, or has an activity as set forth in Table 1. To determine whether a TFSRP or a biologically active portion thereof can participate in transcription of a protein involved in a stress tolerance response in a plant, a stress analysis of a plant expressing the TFSRP may be performed. Such analysis methods are well known to those skilled in the art, as detailed in Example 7.

Additional nucleic acid fragments encoding biologically active portions of a TFSRP can be prepared by isolating a portion of one of the sequences in SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23, expressing the encoded portion of the TFSRP or peptide (e.g., by recombinant expression *in vitro*) and assessing the activity of the encoded portion of the TFSRP or peptide.

The invention further encompasses nucleic acid molecules that differ from one of the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 (and portions thereof) due to degeneracy of the genetic code and thus encode the same TFSRP as that encoded by the nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22. In a further embodiment, the nucleic acid molecule of the invention encodes a full length *Physcomitrella patens* protein which is substantially homologous to an amino acid sequence of a polypeptide shown in SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23.

In addition to the *Physcomitrella patens* TFSRP nucleotide sequences shown in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 and SEQ ID NO:22, it will be appreciated by those skilled in the art that DNA sequence polymorphisms that lead to changes in the amino acid sequences of TFSRPs may exist within a population (e.g., the *Physcomitrella patens* population). Such genetic polymorphism in the TFSRP gene may exist among individuals within a population due to natural variation. As used herein, the terms "gene" and "recombinant gene" refer to nucleic acid molecules comprising an open reading frame encoding a TFSRP, preferably a *Physcomitrella patens* TFSRP. Such natural variations can typically result in 1-5% variance in the nucleotide sequence of the TFSRP gene. Any and all such nucleotide variations and resulting amino acid polymorphisms in a TFSRP that are the result of natural variation and that do not alter the functional activity of the TFSRPs are intended to be within the scope of the invention.

Nucleic acid molecules corresponding to natural variants and non-*Physcomitrella patens* homologues of the *Physcomitrella patens* TFSRP cDNA of the invention can be isolated based on their homology to *Physcomitrella patens* TFSRP nucleic acid disclosed herein using the *Physcomitrella patens* cDNA, or a portion thereof, as a hybridization probe according to standard hybridization techniques under stringent hybridization conditions. Accordingly, in another embodiment, an isolated nucleic acid molecule of the invention is at least 15 nucleotides in length and hybridizes under stringent conditions to the nucleic acid molecule comprising a

nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22. In other embodiments, the nucleic acid is at least 30, 50, 100, 250 or more nucleotides in length. As used herein, the term "hybridizes under stringent conditions" is intended to describe conditions for hybridization and washing under which nucleotide sequences at least 60% homologous to each other typically remain hybridized to each other. Preferably, the conditions are such that sequences at least about 65%, more preferably at least about 70%, and even more preferably at least about 75% or more homologous to each other typically remain hybridized to each other. Such stringent conditions are known to those skilled in the art and can be found in *Current Protocols in Molecular Biology*, 6.3.1-6.3.6, John Wiley & Sons, N.Y. (1989). A preferred, non-limiting example of stringent hybridization conditions are hybridization in 6X sodium chloride/sodium citrate (SSC) at about 45°C, followed by one or more washes in 0.2 X SSC, 0.1% SDS at 50-65°C. Preferably, an isolated nucleic acid molecule of the invention that hybridizes under stringent conditions to a sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 corresponds to a naturally occurring nucleic acid molecule. As used herein, a "naturally-occurring" nucleic acid molecule refers to an RNA or DNA molecule having a nucleotide sequence that occurs in nature (e.g., encodes a natural protein). In one embodiment, the nucleic acid encodes a natural *Physcomitrella patens* TFSRP.

In addition to naturally-occurring variants of the TFSRP sequence that may exist in the population, the skilled artisan will further appreciate that changes can be introduced by mutation into a nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, thereby leading to changes in the amino acid sequence of the encoded TFSRP, without altering the functional ability of the TFSRP. For example, nucleotide substitutions leading to amino acid substitutions at "non-essential" amino acid residues can be made in a sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22. A "non-essential" amino acid residue is a residue that can be altered from the wild-type sequence of one of the TFSRPs (SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 and SEQ ID NO:23)

without altering the activity of said TFSRP, whereas an "essential" amino acid residue is required for TFSRP activity. Other amino acid residues, however, (e.g., those that are not conserved or only semi-conserved in the domain having TFSRP activity) may not be essential for activity and thus are likely to be amenable to alteration without altering TFSRP activity.

Accordingly, another aspect of the invention pertains to nucleic acid molecules encoding TFSRPs that contain changes in amino acid residues that are not essential for TFSRP activity. Such TFSRPs differ in amino acid sequence from a sequence contained in SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23, yet retain at least one of the TFSRP activities described herein. In one embodiment, the isolated nucleic acid molecule comprises a nucleotide sequence encoding a protein, wherein the protein comprises an amino acid sequence at least about 50% homologous to an amino acid sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 and is capable of participating in the a stress tolerance response in a plant, or more particularly participates in the transcription of a protein involved in a stress tolerance response in a *Physcomitrella patens* plant, or has one or more activities set forth in Table 1. Preferably, the protein encoded by the nucleic acid molecule is at least about 50-60% homologous to one of the sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23, more preferably at least about 60-70% homologous to one of the sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23, even more preferably at least about 70-80%, 80-90%, 90-95% homologous to one of the sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23, and most preferably at least about 96%, 97%, 98%, or 99% homologous to one of the sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23.

To determine the percent homology of two amino acid sequences (e.g., one of the sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 and a mutant form

thereof) or of two nucleic acids, the sequences are aligned for optimal comparison purposes (e.g., gaps can be introduced in the sequence of one protein or nucleic acid for optimal alignment with the other protein or nucleic acid). The amino acid residues or nucleotides at corresponding amino acid positions or nucleotide positions are then compared. When a position in one sequence (e.g., one of the sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23) is occupied by the same amino acid residue or nucleotide as the corresponding position in the other sequence (e.g., a mutant form of the sequence selected from the polypeptide of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23), then the molecules are homologous at that position (i.e., as used herein amino acid or nucleic acid "homology" is equivalent to amino acid or nucleic acid "identity"). The percent homology between the two sequences is a function of the number of identical positions shared by the sequences (i.e., % homology = numbers of identical positions/total numbers of positions x 100). Preferably, the length of sequence comparison is at least 15 amino acid residues, more preferably at least 25 amino acid residues, and most preferably at least 35 amino acid residues.

Alternatively, a determination of the percent homology between two sequences can be accomplished using a mathematical algorithm. A preferred, non-limiting example of a mathematical algorithm utilized for the comparison of two sequences is the algorithm of Karlin and Altschul (1990 Proc. Natl. Acad. Sci. USA 90:5873-5877). Such an algorithm is incorporated into the NBLAST and XBLAST programs of Altschul, et al. (1990 J. Mol. Biol. 215:403-410). BLAST nucleic acid searches can be performed with the NBLAST program, score=100, wordlength=12 to obtain nucleic acid sequences homologous to TFSRP nucleic acid molecules of the invention. BLAST protein searches can be performed with the XBLAST program, score=50, wordlength=3 to obtain amino acid sequences homologous to TFSRPs of the present invention. To obtain gapped alignments for comparison purposes, Gapped BLAST can be utilized as described in Altschul et al. (1997 Nucleic Acids Res. 25:3389-3402). When utilizing BLAST and Gapped BLAST programs, the default parameters of the respective programs (e.g., XBLAST and NBLAST) can be used. Another preferred non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the algorithm of Myers and Miller (CABIOS 1989). Such an algorithm is incorporated into the ALIGN program (version 2.0) that is part of the GCG sequence alignment software package. When utilizing the ALIGN program for comparing amino acid sequences, a PAM120 weight residue table, a gap length penalty of 12 and a gap penalty of 4 can be used to obtain amino acid sequences homologous to the

TFSRPs of the present invention. To obtain gapped alignments for comparison purposes, Gapped BLAST can be utilized as described in Altschul et al. (1997 Nucleic Acids Res. 25:3389-3402). When utilizing BLAST and Gapped BLAST programs, the default parameters of the respective programs (e.g., XBLAST and NBLAST) can be used. Another preferred non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the algorithm of Myers and Miller (CABIOS 1989). Such an algorithm is incorporated into the ALIGN program (version 2.0) that is part of the GCG sequence alignment software package. When utilizing the ALIGN program for comparing amino acid sequences, a PAM120 weight residue table, a gap length penalty of 12 and a gap penalty of 4 can be used.

An isolated nucleic acid molecule encoding a TFSRP homologous to a protein sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 can be created by introducing one or more nucleotide substitutions, additions or deletions into a nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 such that one or more amino acid substitutions, additions or deletions are introduced into the encoded protein. Mutations can be introduced into one of the sequences of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 by standard techniques, such as site-directed mutagenesis and PCR-mediated mutagenesis. Preferably, conservative amino acid substitutions are made at one or more predicted non-essential amino acid residues. A "conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined in the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), beta-branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Thus, a predicted nonessential amino acid residue in a TFSRP is preferably replaced with another amino acid residue from the same side chain family. Alternatively, in another embodiment, mutations can be introduced randomly along all or part of a TFSRP coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for a TFSRP activity described herein to identify mutants that retain TFSRP activity. Following mutagenesis of one of the sequences of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10,

SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, the encoded protein can be expressed recombinantly and the activity of the protein can be determined by analyzing the stress tolerance of a plant expressing the protein as described in Example 7.

5 In addition to the nucleic acid molecules encoding TFSRPs described above, another aspect of the invention pertains to isolated nucleic acid molecules that are antisense thereto. An "antisense" nucleic acid comprises a nucleotide sequence that is complementary to a "sense" nucleic acid encoding a protein, e.g., complementary to the coding strand of a double-stranded cDNA molecule or complementary to an mRNA  
10 sequence. Accordingly, an antisense nucleic acid can hydrogen bond to a sense nucleic acid. The antisense nucleic acid can be complementary to an entire TFSRP coding strand, or to only a portion thereof. In one embodiment, an antisense nucleic acid molecule is antisense to a "coding region" of the coding strand of a nucleotide sequence encoding a TFSRP. The term "coding region" refers to the region of the  
15 nucleotide sequence comprising codons which are translated into amino acid residues (e.g., the entire coding region of ,,,, comprises nucleotides 1 to ....). In another embodiment, the antisense nucleic acid molecule is antisense to a "noncoding region" of the coding strand of a nucleotide sequence encoding TFSRP. The term "noncoding region" refers to 5' and 3' sequences that flank the coding region that are not translated  
20 into amino acids (i.e., also referred to as 5' and 3' untranslated regions).

Given the coding strand sequences encoding TFSRP disclosed herein (e.g., the sequences set forth in SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 and SEQ ID NO:22), antisense  
25 nucleic acids of the invention can be designed according to the rules of Watson and Crick base pairing. The antisense nucleic acid molecule can be complementary to the entire coding region of TFSRP mRNA, but more preferably is an oligonucleotide which is antisense to only a portion of the coding or noncoding region of TFSRP mRNA. For example, the antisense oligonucleotide can be complementary to the region surrounding the translation start site of TFSRP mRNA. An antisense  
30 oligonucleotide can be, for example, about 5, 10, 15, 20, 25, 30, 35, 40, 45 or 50 nucleotides in length. An antisense nucleic acid of the invention can be constructed using chemical synthesis and enzymatic ligation reactions using procedures known in the art. For example, an antisense nucleic acid (e.g., an antisense oligonucleotide) can be chemically synthesized using naturally occurring nucleotides or variously modified

nucleotides designed to increase the biological stability of the molecules or to increase the physical stability of the duplex formed between the antisense and sense nucleic acids, e.g., phosphorothioate derivatives and acridine substituted nucleotides can be used. Examples of modified nucleotides which can be used to generate the antisense nucleic acid include 5-fluorouracil, 5-bromouracil, 5-chlorouracil, 5-iodouracil, hypoxanthine, xanthine, 4-acetylcytosine, 5-(carboxyhydroxymethyl) uracil, 5-carboxymethylaminomethyl-2-thiouridine, 5-carboxymethylaminomethyluracil, dihydrouracil, beta-D-galactosylqueosine, inosine, N6-isopentenyladenine, 1-methylguanine, 1-methylinosine, 2,2-dimethylguanine, 2-methyladenine, 2-methylguanine, 3-methylcytosine, 5-methylcytosine, N6-adenine, 7-methylguanine, 5-methylaminomethyluracil, 5-methoxyaminomethyl-2-thiouracil, beta-D-mannosylqueosine, 5'-methoxycarboxymethyluracil, 5-methoxyuracil, 2-methylthio-N6-isopentenyladenine, uracil-5-oxyacetic acid (v), wybutoxosine, pseudouracil, queosine, 2-thiocytosine, 5-methyl-2-thiouracil, 2-thiouracil, 4-thiouracil, 5-methyluracil, uracil-5-oxyacetic acid methylester, uracil-5-oxyacetic acid (v), 5-methyl-2-thiouracil, 3-(3-amino-3-N-2-carboxypropyl) uracil, (acp3)w, and 2,6-diaminopurine. Alternatively, the antisense nucleic acid can be produced biologically using an expression vector into which a nucleic acid has been subcloned in an antisense orientation (i.e., RNA transcribed from the inserted nucleic acid will be of an antisense orientation to a target nucleic acid of interest, described further in the following subsection).

The antisense nucleic acid molecules of the invention are typically administered to a cell or generated *in situ* such that they hybridize with or bind to cellular mRNA and/or genomic DNA encoding a TFSRP to thereby inhibit expression of the protein, e.g., by inhibiting transcription and/or translation. The hybridization can be by conventional nucleotide complementarity to form a stable duplex, or, for example, in the case of an antisense nucleic acid molecule which binds to DNA duplexes, through specific interactions in the major groove of the double helix. The antisense molecule can be modified such that it specifically binds to a receptor or an antigen expressed on a selected cell surface, e.g., by linking the antisense nucleic acid molecule to a peptide or an antibody which binds to a cell surface receptor or antigen. The antisense nucleic acid molecule can also be delivered to cells using the vectors described herein. To achieve sufficient intracellular concentrations of the antisense

molecules, vector constructs in which the antisense nucleic acid molecule is placed under the control of a strong prokaryotic, viral, or eukaryotic (including plant) promoters are preferred.

In yet another embodiment, the antisense nucleic acid molecule of the invention is an  $\alpha$ -anomeric nucleic acid molecule. An  $\alpha$ -anomeric nucleic acid molecule forms specific double-stranded hybrids with complementary RNA in which, contrary to the usual  $\beta$ -units, the strands run parallel to each other (Gaultier et al., 1987 Nucleic Acids. Res. 15:6625-6641). The antisense nucleic acid molecule can also comprise a 2'-o-methylribonucleotide (Inoue et al., 1987 Nucleic Acids Res. 15:6131-6148) or a chimeric RNA-DNA analogue (Inoue et al., 1987 FEBS Lett. 215:327-330).

In still another embodiment, an antisense nucleic acid of the invention is a ribozyme. Ribozymes are catalytic RNA molecules with ribonuclease activity which are capable of cleaving a single-stranded nucleic acid, such as an mRNA, to which they have a complementary region. Thus, ribozymes (e.g., hammerhead ribozymes (described in Haselhoff and Gerlach, 1988 Nature 334:585-591)) can be used to catalytically cleave TFSRP mRNA transcripts to thereby inhibit translation of TFSRP mRNA. A ribozyme having specificity for a TFSRP-encoding nucleic acid can be designed based upon the nucleotide sequence of a TFSRP cDNA disclosed herein (i.e., SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22) or on the basis of a heterologous sequence to be isolated according to methods taught in this invention. For example, a derivative of a *Tetrahymena* L-19 IVS RNA can be constructed in which the nucleotide sequence of the active site is complementary to the nucleotide sequence to be cleaved in an TFSRP-encoding mRNA. See, e.g., Cech et al. U.S. Patent No. 4,987,071 and Cech et al. U.S. Patent No. 5,116,742. Alternatively, TFSRP mRNA can be used to select a catalytic RNA having a specific ribonuclease activity from a pool of RNA molecules. See, e.g., Bartel, D. and Szostak, J.W., 1993 Science 261:1411-1418.

Alternatively, TFSRP gene expression can be inhibited by targeting nucleotide sequences complementary to the regulatory region of a TFSRP nucleotide sequence (e.g., a TFSRP promoter and/or enhancer) to form triple helical structures that prevent transcription of an TFSRP gene in target cells. See generally, Helene, C., 1991

Anticancer Drug Des. 6(6):569-84; Helene, C. et al., 1992 Ann. N.Y. Acad. Sci. 660:27-36; and Maher, L.J., 1992 Bioassays 14(12):807-15.

The invention further provides an isolated recombinant expression vector comprising a nucleic acid as described above, wherein expression of the vector in a host cell results in increased tolerance to environmental stress as compared to a wild type variety of the host cell. As used herein, the term "vector" refers to a nucleic acid molecule capable of transporting another nucleic acid to which it has been linked. One type of vector is a "plasmid", which refers to a circular double stranded DNA loop into which additional DNA segments can be ligated. Another type of vector is a viral vector, wherein additional DNA segments can be ligated into the viral genome. Certain vectors are capable of autonomous replication in a host cell into which they are introduced (e.g., bacterial vectors having a bacterial origin of replication and episomal mammalian vectors). Other vectors (e.g., non-episomal mammalian vectors) are integrated into the genome of a host cell upon introduction into the host cell, and thereby are replicated along with the host genome. Moreover, certain vectors are capable of directing the expression of genes to which they are operatively linked. Such vectors are referred to herein as "expression vectors". In general, expression vectors of utility in recombinant DNA techniques are often in the form of plasmids. In the present specification, "plasmid" and "vector" can be used interchangeably as the plasmid is the most commonly used form of vector. However, the invention is intended to include such other forms of expression vectors, such as viral vectors (e.g., replication defective retroviruses, adenoviruses and adeno-associated viruses), which serve equivalent functions.

The recombinant expression vectors of the invention comprise a nucleic acid of the invention in a form suitable for expression of the nucleic acid in a host cell, which means that the recombinant expression vectors include one or more regulatory sequences, selected on the basis of the host cells to be used for expression, which is operatively linked to the nucleic acid sequence to be expressed. Within a recombinant expression vector, "operably linked" is intended to mean that the nucleotide sequence of interest is linked to the regulatory sequence(s) in a manner which allows for expression of the nucleotide sequence (e.g., in an *in vitro* transcription/ translation system or in a host cell when the vector is introduced into the host cell). The term "regulatory sequence" is intended to include promoters, enhancers and other expression

control elements (e.g., polyadenylation signals). Such regulatory sequences are described, for example, in Goeddel, Gene Expression Technology: Methods in Enzymology 185, Academic Press, San Diego, CA (1990) or see: Gruber and Crosby, in: Methods in Plant Molecular Biology and Biotechnology, eds. Glick and Thompson, Chapter 7, 89-108, CRC Press: Boca Raton, Florida, including the references therein. Regulatory sequences include those that direct constitutive expression of a nucleotide sequence in many types of host cells and those that direct expression of the nucleotide sequence only in certain host cells or under certain conditions. It will be appreciated by those skilled in the art that the design of the expression vector can depend on such factors as the choice of the host cell to be transformed, the level of expression of protein desired, etc. The expression vectors of the invention can be introduced into host cells to thereby produce proteins or peptides, including fusion proteins or peptides, encoded by nucleic acids as described herein (e.g., TFSRPs, mutant forms of TFSRPs, fusion proteins, etc.).

The recombinant expression vectors of the invention can be designed for expression of TFSRPs in prokaryotic or eukaryotic cells. For example, TFSRP genes can be expressed in bacterial cells such as *C. glutamicum*, insect cells (using baculovirus expression vectors), yeast and other fungal cells (see Romanos, M.A. et al., 1992 Foreign gene expression in yeast: a review, Yeast 8:423-488; van den Hondel, C.A.M.J.J. et al., 1991 Heterologous gene expression in filamentous fungi, in: More Gene Manipulations in Fungi, J.W. Bennet & L.L. Lasure, eds., p. 396-428: Academic Press: San Diego; and van den Hondel, C.A.M.J.J. & Punt, P.J., 1991 Gene transfer systems and vector development for filamentous fungi, in: Applied Molecular Genetics of Fungi, Peberdy, J.F. et al., eds., p. 1-28, Cambridge University Press: Cambridge), algae (Falcitatore et al., 1999 Marine Biotechnology 1(3):239-251), ciliates of the types: Holotrichia, Peritrichia, Spirotrichia, Suctoria, Tetrahymena, Paramecium, Colpidium, Glaucoma, Platyophrya, Potomacus, Pseudocohnilembus, Euplotes, Engelmaniella, and Stylonychia, especially of the genus Stylonychia lemnae with vectors following a transformation method as described in WO 98/01572 and multicellular plant cells (see Schmidt, R. and Willmitzer, L., 1988 High efficiency *Agrobacterium tumefaciens*-mediated transformation of *Arabidopsis thaliana* leaf and cotyledon explants, Plant Cell Rep. 583-586; Plant Molecular Biology and Biotechnology, C Press, Boca Raton, Florida, chapter 6/7, S.71-119 (1993); F.F. White, B. Jenes et al., Techniques for Gene

Transfer, in: *Transgenic Plants*, Vol. 1, Engineering and Utilization, eds. Kung and R. Wu, 128-43, Academic Press: 1993; Potrykus, 1991 *Annu. Rev. Plant Physiol. Plant Molec. Biol.* 42:205-225 and references cited therein) or mammalian cells. Suitable host cells are discussed further in Goeddel, *Gene Expression Technology: Methods in Enzymology* 185, Academic Press: San Diego, CA (1990). Alternatively, the recombinant expression vector can be transcribed and translated *in vitro*, for example using T7 promoter regulatory sequences and T7 polymerase.

Expression of proteins in prokaryotes is most often carried out with vectors containing constitutive or inducible promoters directing the expression of either fusion or non-fusion proteins. Fusion vectors add a number of amino acids to a protein encoded therein, usually to the amino terminus of the recombinant protein but also to the C-terminus or fused within suitable regions in the proteins. Such fusion vectors typically serve three purposes: 1) to increase expression of recombinant protein; 2) to increase the solubility of the recombinant protein; and 3) to aid in the purification of the recombinant protein by acting as a ligand in affinity purification. Often, in fusion expression vectors, a proteolytic cleavage site is introduced at the junction of the fusion moiety and the recombinant protein to enable separation of the recombinant protein from the fusion moiety subsequent to purification of the fusion protein. Such enzymes, and their cognate recognition sequences, include Factor Xa, thrombin and enterokinase.

Typical fusion expression vectors include pGEX (Pharmacia Biotech Inc; Smith, D.B. and Johnson, K.S., 1988 *Gene* 67:31-40), pMAL (New England Biolabs, Beverly, MA) and pRIT5 (Pharmacia, Piscataway, NJ) which fuse glutathione S-transferase (GST), maltose E binding protein, or protein A, respectively, to the target recombinant protein. In one embodiment, the coding sequence of the TFSRP is cloned into a pGEX expression vector to create a vector encoding a fusion protein comprising, from the N-terminus to the C-terminus, GST-thrombin cleavage site-X protein. The fusion protein can be purified by affinity chromatography using glutathione-agarose resin. Recombinant TFSRP unfused to GST can be recovered by cleavage of the fusion protein with thrombin.

Examples of suitable inducible non-fusion *E. coli* expression vectors include pTrc (Amann et al., 1988 *Gene* 69:301-315) and pET '11d (Studier et al., *Gene Expression Technology: Methods in Enzymology* 185, Academic Press, San Diego,

California (1990) 60-89). Target gene expression from the pTrc vector relies on host RNA polymerase transcription from a hybrid trp-lac fusion promoter. Target gene expression from the pET 11d vector relies on transcription from a T7 gn10-lac fusion promoter mediated by a co-expressed viral RNA polymerase (T7 gn1). This viral  
5 polymerase is supplied by host strains BL21(DE3) or HMS174(DE3) from a resident  $\lambda$  prophage harboring a T7 gn1 gene under the transcriptional control of the lacUV 5 promoter.

One strategy to maximize recombinant protein expression is to express the protein in a host bacteria with an impaired capacity to proteolytically cleave the  
10 recombinant protein (Gottesman, S., *Gene Expression Technology: Methods in Enzymology* 185, Academic Press, San Diego, California (1990) 119-128). Another strategy is to alter the nucleic acid sequence of the nucleic acid to be inserted into an expression vector so that the individual codons for each amino acid are those preferentially utilized in the bacterium chosen for expression, such as *C. glutamicum*  
15 (Wada et al., 1992 Nucleic Acids Res. 20:2111-2118). Such alteration of nucleic acid sequences of the invention can be carried out by standard DNA synthesis techniques.

In another embodiment, the TFSRP expression vector is a yeast expression vector. Examples of vectors for expression in yeast *S. cerevisiae* include pYepSec1 (Baldari, et al., 1987 Embo J. 6:229-234), pMFa (Kurjan and Herskowitz, 1982 Cell  
20 30:933-943), pJRY88 (Schultz et al., 1987 Gene 54:113-123), and pYES2 (Invitrogen Corporation, San Diego, CA). Vectors and methods for the construction of vectors appropriate for use in other fungi, such as the filamentous fungi, include those detailed in: van den Hondel, C.A.M.J.J. & Punt, P.J. (1991) "Gene transfer systems and vector development for filamentous fungi, in: Applied Molecular Genetics of Fungi, J.F.  
25 Peberdy, et al., eds., p. 1-28, Cambridge University Press: Cambridge.

Alternatively, the TFSRPs of the invention can be expressed in insect cells using baculovirus expression vectors. Baculovirus vectors available for expression of proteins in cultured insect cells (e.g., Sf 9 cells) include the pAc series (Smith et al., 1983 Mol. Cell Biol. 3:2156-2165) and the pVL series (Lucklow and Summers, 1989  
30 Virology 170:31-39).

In yet another embodiment, a nucleic acid of the invention is expressed in mammalian cells using a mammalian expression vector. Examples of mammalian expression vectors include pCDM8 (Seed, B., 1987 Nature 329:840) and pMT2PC

(Kaufman et al., 1987 EMBO J. 6:187-195). When used in mammalian cells, the expression vector's control functions are often provided by viral regulatory elements. For example, commonly used promoters are derived from polyoma, Adenovirus 2, cytomegalovirus and Simian Virus 40. For other suitable expression systems for both  
5 prokaryotic and eukaryotic cells see chapters 16 and 17 of Sambrook, J., Fritsch, E. F., and Maniatis, T. *Molecular Cloning: A Laboratory Manual*. 2nd, ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989.

In another embodiment, the recombinant mammalian expression vector is  
10 capable of directing expression of the nucleic acid preferentially in a particular cell type (e.g., tissue-specific regulatory elements are used to express the nucleic acid). Tissue-specific regulatory elements are known in the art. Non-limiting examples of suitable tissue-specific promoters include the albumin promoter (liver-specific; Pinkert et al., 1987 Genes Dev. 1:268-277), lymphoid-specific promoters (Calame and Eaton,  
15 1988 Adv. Immunol. 43:235-275), in particular promoters of T cell receptors (Winoto and Baltimore, 1989 EMBO J. 8:729-733) and immunoglobulins (Banerji et al., 1983 Cell 33:729-740; Queen and Baltimore, 1983 Cell 33:741-748), neuron-specific promoters (e.g., the neurofilament promoter; Byrne and Ruddie, 1989 PNAS 86:5473-5477), pancreas-specific promoters (Edlund et al., 1985 Science 230:912-916), and  
20 mammary gland-specific promoters (e.g., milk whey promoter; U.S. Patent No. 4,873,316 and European Application Publication No. 264,166). Developmentally-regulated promoters are also encompassed, for example the murine hox promoters (Kessel and Gruss, 1990 Science 249:374-379) and the fetoprotein promoter (Campes and Tilghman, 1989 Genes Dev. 3:537-546).

In another embodiment, the TFSRPs of the invention may be expressed in  
25 unicellular plant cells (such as algae) (see Falcatore et al., 1999 Marine Biotechnology 1(3):239-251 and references therein) and plant cells from higher plants (e.g., the spermatophytes, such as crop plants). Examples of plant expression vectors include those detailed in: Becker, D., Kemper, E., Schell, J. and Masterson, R., 1992 New  
30 plant binary vectors with selectable markers located proximal to the left border, *Plant Mol. Biol.* 20: 1195-1197; and Bevan, M.W., 1984 Binary *Agrobacterium* vectors for plant transformation, *Nucl. Acid. Res.* 12:8711-8721; Vectors for Gene Transfer in

Higher Plants; in: Transgenic Plants, Vol. 1, Engineering and Utilization, eds.: Kung and R. Wu, Academic Press, 1993, S. 15-38.

A plant expression cassette preferably contains regulatory sequences capable of driving gene expression in plants cells and which are operably linked so that each  
5 sequence can fulfill its function, for example, termination of transcription by polyadenylation signals. Preferred polyadenylation signals are those originating from *Agrobacterium tumefaciens* t-DNA such as the gene 3 known as octopine synthase of the Ti-plasmid pTiACH5 (Gielen et al., 1984 EMBO J. 3:835) or functional equivalents thereof but also all other terminators functionally active in plants are suitable.

As plant gene expression is very often not limited on transcriptional levels, a plant expression cassette preferably contains other operably linked sequences like translational enhancers such as the overdrive-sequence containing the 5'-untranslated leader sequence from tobacco mosaic virus enhancing the protein per RNA ratio  
15 (Gallie et al., 1987 Nucl. Acids Research 15:8693-8711).

Plant gene expression has to be operably linked to an appropriate promoter conferring gene expression in a timely, cell or tissue specific manner. Preferred are promoters driving constitutive expression (Benfey et al., 1989 EMBO J. 8:2195-2202) like those derived from plant viruses like the 35S CAMV (Franck et al., 1980 Cell  
20 21:285-294), the 19S CaMV (see also US Patent No. 5352605 and WO8402913) or plant promoters like those from Rubisco small subunit described in US Patent No. 4962028.

Other preferred sequences for use in plant gene expression cassettes are targeting-sequences necessary to direct the gene product in its appropriate cell  
25 compartment (for review see Kermode, 1996 Crit. Rev. Plant Sci. 15(4):285-423 and references cited therein) such as the vacuole, the nucleus, all types of plastids like amyloplasts, chloroplasts, chromoplasts, the extracellular space, mitochondria, the endoplasmic reticulum, oil bodies, peroxisomes and other compartments of plant cells.

Plant gene expression can also be facilitated via an inducible promoter (for review see Gatz, 1997 Annu. Rev. Plant Physiol. Plant Mol. Biol. 48:89-108). Chemically inducible promoters are especially suitable if gene expression is wanted to occur in a time specific manner. Examples of such promoters are a salicylic acid

inducible promoter (WO 95/19443), a tetracycline inducible promoter (Gatz et al., 1992 Plant J. 2:397-404) and an ethanol inducible promoter (WO 93/21334).

Also, suitable promoters responding to biotic or abiotic stress conditions are those such as the pathogen inducible PRP1-gene promoter (Ward et al., 1993 Plant Mol. Biol. 22:361-366), the heat inducible hsp80-promoter from tomato (US Patent No. 5187267), cold inducible alpha-amylase promoter from potato (WO 96/12814) or the wound-inducible pinII-promoter (EP 375091). For other examples of drought, cold, and salt-inducible promoters, such as the RD29A promoter, see Yamaguchi-Shinozaki et al. (1993 Mol. Gen. Genet. 236:331-340).

Especially those promoters are preferred which confer gene expression in specific tissues and organs, such as guard cells and the root hair cells. Suitable promoters include the napin-gene promoter from rapeseed (US Patent No. 5608152), the USP-promoter from *Vicia faba* (Baeumlein et al., 1991 Mol Gen Genet. 225(3):459-67), the oleosin-promoter from *Arabidopsis* (WO9845461), the phaseolin-promoter from *Phaseolus vulgaris* (US Patent No. 5504200), the Bce4-promoter from Brassica (WO9113980) or the legumin B4 promoter (LeB4; Baeumlein et al., 1992 Plant Journal, 2(2):233-9) as well as promoters conferring seed specific expression in monocot plants like maize, barley, wheat, rye, rice, etc. Suitable promoters to note are the lpt2 or lpt1-gene promoter from barley (WO 95/15389 and WO 95/23230) or those described in WO 99/16890 (promoters from the barley hordein-gene, rice glutelin gene, rice oryza gene, rice prolamin gene, wheat gliadin gene, wheat glutelin gene, maize zein gene, oat glutelin gene, Sorghum kafirin-gene and rye secalin gene).

Also especially suited are promoters that confer plastid-specific gene expression as plastids are the compartment where precursors and some end products of lipid biosynthesis are synthesized. Suitable promoters are the viral RNA-polymerase promoter described in WO 95/16783 and WO 97/06250 and the clpP-promoter from *Arabidopsis* described in WO 99/46394.

The invention further provides a recombinant expression vector comprising a DNA molecule of the invention cloned into the expression vector in an antisense orientation. That is, the DNA molecule is operatively linked to a regulatory sequence in a manner that allows for expression (by transcription of the DNA molecule) of an RNA molecule that is antisense to TFSRP mRNA. Regulatory sequences operatively linked to a nucleic acid molecule cloned in the antisense orientation can be chosen

which direct the continuous expression of the antisense RNA molecule in a variety of cell types. For instance viral promoters and/or enhancers, or regulatory sequences can be chosen which direct constitutive, tissue specific or cell type specific expression of antisense RNA. The antisense expression vector can be in the form of a recombinant plasmid, phagemid or attenuated virus in which antisense nucleic acids are produced under the control of a high efficiency regulatory region, the activity of which can be determined by the cell type into which the vector is introduced. For a discussion of the regulation of gene expression using antisense genes see Weintraub, H. et al., Antisense RNA as a molecular tool for genetic analysis, *Reviews - Trends in Genetics*, Vol. 1(1) 1986 and Mol et al., 1990 *FEBS Letters* 268:427-430.

Another aspect of the invention pertains to host cells into which a recombinant expression vector of the invention has been introduced. The terms "host cell" and "recombinant host cell" are used interchangeably herein. It is understood that such terms refer not only to the particular subject cell but they also apply to the progeny or potential progeny of such a cell. Because certain modifications may occur in succeeding generations due to either mutation or environmental influences, such progeny may not, in fact, be identical to the parent cell, but are still included within the scope of the term as used herein.

A host cell can be any prokaryotic or eukaryotic cell. For example, a TFSRP can be expressed in bacterial cells such as *C. glutamicum*, insect cells, fungal cells or mammalian cells (such as Chinese hamster ovary cells (CHO) or COS cells), algae, ciliates, plant cells, fungi or other microorganisms like *C. glutamicum*. Other suitable host cells are known to those skilled in the art.

Vector DNA can be introduced into prokaryotic or eukaryotic cells via conventional transformation or transfection techniques. As used herein, the terms "transformation", "transfection", "conjugation" and "transduction" are intended to refer to a variety of art-recognized techniques for introducing foreign nucleic acid (e.g., DNA) into a host cell, including calcium phosphate or calcium chloride co-precipitation, DEAE-dextran-mediated transfection, lipofection, natural competence, chemical-mediated transfer and electroporation. Suitable methods for transforming or transfecting host cells including plant cells can be found in Sambrook, et al. (*Molecular Cloning: A Laboratory Manual*, 2nd, ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989) and

other laboratory manuals such as *Methods in Molecular Biology*, 1995, Vol. 44, *Agrobacterium* protocols, ed: Gartland and Davey, Humana Press, Totowa, New Jersey. As biotic and abiotic stress tolerance is a general trait wished to be inherited into a wide variety of plants like maize, wheat, rye, oat, triticale, rice, barley, soybean, peanut, cotton, rapeseed and canola, manihot, pepper, sunflower and tagetes, solanaceous plants like potato, tobacco, eggplant, and tomato, *Vicia* species, pea, alfalfa, bushy plants (coffee, cacao, tea), *Salix* species, trees (oil palm, coconut), perennial grasses and forage crops, these crops plants are also preferred target plants for a genetic engineering as one further embodiment of the present invention.

In particular, the invention provides a method of producing a transgenic plant with a TFSRP coding nucleic acid, wherein expression of the nucleic acid in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant comprising: (a) transforming a plant cell with an expression vector comprising a TFSRP nucleic acid, and (b) generating from the plant cell a transgenic plant with a increased tolerance to environmental stress as compared to a wild type variety of the plant. In preferred embodiments, the TFSRP is as described above. In preferred embodiments, the TFSRP coding nucleic acid is as described above. The invention also provides a method of increasing expression of a gene of interest within a host cell as compared to a wild type variety of the host cell, wherein the gene of interest is transcribed in response to a TFSRP, comprising: (a) transforming the host cell with an expression vector comprising a TFSRP coding nucleic acid, and (b) expressing the TFSRP within the host cell, thereby increasing the expression of the gene transcribed in response to the TFSRP as compared to a wild type variety of the host cell. In preferred embodiments, the TFSRP is as described above. In preferred embodiments, the TFSRP coding nucleic acid is as described above.

For such plant transformation, binary vectors such as pBinAR can be used (Höfgen and Willmitzer, 1990 *Plant Science* 66:221-230). Construction of the binary vectors can be performed by ligation of the cDNA in sense or antisense orientation into the T-DNA. 5-prime to the cDNA a plant promoter activates transcription of the cDNA. A polyadenylation sequence is located 3-prime to the cDNA. Tissue-specific expression can be archived by using a tissue specific promoter. For example, seed-specific expression can be archived by cloning the napin or LeB4 or USP promoter 5-prime to the cDNA. Also, any other seed specific promoter element can be used. For

constitutive expression within the whole plant, the CaMV 35S promoter can be used. The expressed protein can be targeted to a cellular compartment using a signal peptide, for example for plastids, mitochondria or endoplasmic reticulum (Kermode, Crit. Rev. Plant Sci., 1996 4 (15):285-423). The signal peptide is cloned 5-prime in frame to the cDNA to archive subcellular localization of the fusion protein.

Agrobacterium mediated plant transformation can be performed using for example the GV3101(pMP90) (Koncz and Schell, 1986 Mol. Gen. Genet. 204:383-396) or LBA4404 (Clontech) Agrobacterium tumefaciens strain. Transformation can be performed by standard transformation techniques (Deblaere et al., 1994 Nucl. Acids. Res. 13:4777-4788). In one embodiment, promoters that are responsive to abiotic stresses can be used with, such as the *Arabidopsis* promoter RD29A, the nucleic acid sequences disclosed herein. One skilled in the art will recognize that the promoter used should be operatively linked to the nucleic acid such that the promoter causes transcription of the nucleic acid which results in the synthesis of a mRNA which encodes a polypeptide. Alternatively, the RNA can be an antisense RNA for use in affecting subsequent expression of the same or another gene or genes.

Agrobacterium mediated plant transformation can be performed using standard transformation and regeneration techniques (Gelvin, Stanton B. and Schilperoort, Robert A, Plant Molecular Biology Manual, 2nd Ed. - Dordrecht : Kluwer Academic Publ., 1995. - in Sect. Ringbuc Zentrale Signatur: BT11-P ISBN 0-7923-2731-4; Glick, Bernard R.; Thompson, John E., Methods in Plant Molecular Biology and Biotechnology, Boca Raton : CRC Press, 1993. - 360 S., ISBN 0-8493-5164-2). For example, rapeseed can be transformed via cotyledon or hypocotyl transformation (Moloney et al., 1989 Plant cell Report 8:238-242; De Block et al., 1989 Plant Physiol. 91:694-701). Use of antibiotics for Agrobacterium and plant selection depends on the binary vector and the Agrobacterium strain used for transformation. Rapeseed selection is normally performed using kanamycin as selectable plant marker. Agrobacterium mediated gene transfer to flax can be performed using, for example, a technique described by Mlynarova et al., 1994 Plant Cell Report 13: 282-285. Additionally, transformation of soybean can be performed using for example a technique described in EP 0424 047, US Patent No. 5322783 (Pioneer Hi-Bred International) or in EP 0397 687, US Patent No. 5376543, US Patent No. 5169770 (University Toledo).

Plant transformation using particle bombardment, Polyethylene Glycol mediated DNA uptake or via the Silicon Carbide Fiber technique is for example described by Freeling and Walbot "The maize handbook" Springer Verlag: New York (1993) ISBN 3-540-97826-7. A specific example of maize transformation is found in US 5,990,387 and a specific example of wheat transformation can be found in WO 93/07256.

For stable transfection of mammalian cells, it is known that, depending upon the expression vector and transfection technique used, only a small fraction of cells may integrate the foreign DNA into their genome. In order to identify and select these integrants, a gene that encodes a selectable marker (e.g., resistance to antibiotics) is generally introduced into the host cells along with the gene of interest. Preferred selectable markers include those which confer resistance to drugs, such as G418, hygromycin and methotrexate or in plants that confer resistance towards a herbicide such as glyphosate or glufosinate. Nucleic acid molecules encoding a selectable marker can be introduced into a host cell on the same vector as that encoding an TFSRP or can be introduced on a separate vector. Cells stably transfected with the introduced nucleic acid molecule can be identified by, for example, drug selection (e.g., cells that have incorporated the selectable marker gene will survive, while the other cells die).

To create a homologous recombinant microorganism, a vector is prepared which contains at least a portion of a TFSRP gene into which a deletion, addition or substitution has been introduced to thereby alter, e.g., functionally disrupt, the TFSRP gene. Preferably, this TFSRP gene is a *Physcomitrella patens* TFSRP gene, but it can be a homologue from a related plant or even from a mammalian, yeast, or insect source. In a preferred embodiment, the vector is designed such that, upon homologous recombination, the endogenous TFSRP gene is functionally disrupted (i.e., no longer encodes a functional protein; also referred to as a knock-out vector). Alternatively, the vector can be designed such that, upon homologous recombination, the endogenous TFSRP gene is mutated or otherwise altered but still encodes functional protein (e.g., the upstream regulatory region can be altered to thereby alter the expression of the endogenous TFSRP). To create a point mutation via homologous recombination, DNA-RNA hybrids can be used in a technique known as chimeraplasty (Cole-Strauss et al., 1999 Nucleic Acids Research 27(5):1323-1330 and Kmiec, 1999 Gene therapy

American Scientist. 87(3):240-247). Homologous recombination procedures in *Physcomitrella patens* are also well known in the art and are contemplated for use herein.

Whereas in the homologous recombination vector, the altered portion of the TFSRP gene is flanked at its 5' and 3' ends by additional nucleic acid molecule of the TFSRP gene to allow for homologous recombination to occur between the exogenous TFSRP gene carried by the vector and an endogenous TFSRP gene in a microorganism or plant. The additional flanking TFSRP nucleic acid molecule is of sufficient length for successful homologous recombination with the endogenous gene. Typically, several hundreds of base pairs up to kilobases of flanking DNA (both at the 5' and 3' ends) are included in the vector (see e.g., Thomas, K.R., and Capecchi, M.R., 1987 Cell 51:503 for a description of homologous recombination vectors or Strepp et al., 1998 PNAS, 95 (8):4368-4373 for cDNA based recombination in *Physcomitrella patens*). The vector is introduced into a microorganism or plant cell (e.g., via polyethylene glycol mediated DNA) and cells in which the introduced TFSRP gene has homologously recombined with the endogenous TFSRP gene are selected, using art-known techniques.

In another embodiment, recombinant microorganisms can be produced which contain selected systems which allow for regulated expression of the introduced gene. For example, inclusion of a TFSRP gene on a vector placing it under control of the lac operon permits expression of the TFSRP gene only in the presence of IPTG. Such regulatory systems are well known in the art.

A host cell of the invention, such as a prokaryotic or eukaryotic host cell in culture, can be used to produce (i.e., express) a TFSRP. An alternate method can be applied in addition in plants by the direct transfer of DNA into developing flowers via electroporation or Agrobacterium medium gene transfer. Accordingly, the invention further provides methods for producing TFSRPs using the host cells of the invention. In one embodiment, the method comprises culturing the host cell of invention (into which a recombinant expression vector encoding a TFSRP has been introduced, or into which genome has been introduced a gene encoding a wild-type or altered TFSRP) in a suitable medium until TFSRP is produced. In another embodiment, the method further comprises isolating TFSRPs from the medium or the host cell.

Another aspect of the invention pertains to isolated TFSRPs, and biologically active portions thereof. An "isolated" or "purified" protein or biologically active portion thereof is free of some of the cellular material when produced by recombinant DNA techniques, or chemical precursors or other chemicals when chemically synthesized. The language "substantially free of cellular material" includes preparations of TFSRP in which the protein is separated from some of the cellular components of the cells in which it is naturally or recombinantly produced. In one embodiment, the language "substantially free of cellular material" includes preparations of TFSRP having less than about 30% (by dry weight) of non-TFSRP (also referred to herein as a "contaminating protein"), more preferably less than about 20% of non-TFSRP, still more preferably less than about 10% of non-TFSRP, and most preferably less than about 5% non-TFSRP. When the TFSRP or biologically active portion thereof is recombinantly produced, it is also preferably substantially free of culture medium, i.e., culture medium represents less than about 20%, more preferably less than about 10%, and most preferably less than about 5% of the volume of the protein preparation. The language "substantially free of chemical precursors or other chemicals" includes preparations of TFSRP in which the protein is separated from chemical precursors or other chemicals that are involved in the synthesis of the protein. In one embodiment, the language "substantially free of chemical precursors or other chemicals" includes preparations of TFSRP having less than about 30% (by dry weight) of chemical precursors or non-TFSRP chemicals, more preferably less than about 20% chemical precursors or non-TFSRP chemicals, still more preferably less than about 10% chemical precursors or non-TFSRP chemicals, and most preferably less than about 5% chemical precursors or non-TFSRP chemicals. In preferred embodiments, isolated proteins or biologically active portions thereof lack contaminating proteins from the same organism from which the TFSRP is derived. Typically, such proteins are produced by recombinant expression of, for example, a *Physcomitrella patens* TFSRP in plants other than *Physcomitrella patens* or microorganisms such as *C. glutamicum*, ciliates, algae or fungi.

An isolated TFSRP or a portion thereof of the invention can participate in a stress tolerance response in a plant, or more particularly can participate in the transcription of a protein involved in a stress tolerance response in a *Physcomitrella patens* plant, or has one or more of the activities set forth in Table 1. In preferred

embodiments, the protein or portion thereof comprises an amino acid sequence which is sufficiently homologous to an amino acid sequence encoded by a nucleic acid of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22 such that the protein or portion thereof maintains the ability to participate in the metabolism of compounds necessary for the construction of cellular membranes in *Physcomitrella patens*, or in the transport of molecules across these membranes. The portion of the protein is preferably a biologically active portion as described herein. In another preferred embodiment, a TFSRP of the invention has an amino acid sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23. In yet another preferred embodiment, the TFSRP has an amino acid sequence which is encoded by a nucleotide sequence which hybridizes, e.g., hybridizes under stringent conditions, to a nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22. In still another preferred embodiment, the TFSRP has an amino acid sequence which is at least about 50-60%, preferably at least about 60-70%, more preferably at least about 70-80%, 80-90%, 90-95%, and even more preferably at least about 96%, 97%, 98%, 99% or more homologous to one of the amino acid sequences of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23. The preferred TFSRPs of the present invention also preferably possess at least one of the TFSRP activities described herein. For example, a preferred TFSRP of the present invention includes an amino acid sequence encoded by a nucleotide sequence which hybridizes, e.g., hybridizes under stringent conditions, to a nucleotide sequence of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22, and which can participate in a stress tolerance response in a plant, or more particularly can participate in the transcription of a protein involved in a stress tolerance response in a *Physcomitrella patens* plant, or which has one or more of the activities set forth in Table 1.

In other embodiments, the TFSRP is substantially homologous to an amino acid sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 and retains the functional activity of the protein of one of the sequences of SEQ ID NO:15, SEQ ID

NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23, yet differs in amino acid sequence due to natural variation or mutagenesis, as described in detail above. Accordingly, in another embodiment, the TFSRP is a protein which comprises an amino acid sequence which is at least about  
5 50-60%, preferably at least about 60-70%, and more preferably at least about 70-80, 80-90, 90-95%, and most preferably at least about 96%, 97%, 98%, 99% or more homologous to an entire amino acid sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 and which has at least one of the TFSRP activities described herein. In  
10 another embodiment, the invention pertains to a full *Physcomitrella patens* protein which is substantially homologous to an entire amino acid sequence encoded by a nucleic acid of SEQ ID NO:8, SEQ ID NO:9, SEQ ID NO:10, SEQ ID NO:11, SEQ ID NO:12, SEQ ID NO:13, SEQ ID NO:14 or SEQ ID NO:22.

Biologically active portions of an TFSRP include peptides comprising amino  
15 acid sequences derived from the amino acid sequence of an TFSRP, e.g., an amino acid sequence of SEQ ID NO:15, SEQ ID NO:16, SEQ ID NO:17, SEQ ID NO:18, SEQ ID NO:19, SEQ ID NO:20, SEQ ID NO:21 or SEQ ID NO:23 or the amino acid sequence of a protein homologous to an TFSRP, which include fewer amino acids than a full length TFSRP or the full length protein which is homologous to an TFSRP, and exhibit  
20 at least one activity of an TFSRP. Typically, biologically active portions (peptides, e.g., peptides which are, for example, 5, 10, 15, 20, 30, 35, 36, 37, 38, 39, 40, 50, 100 or more amino acids in length) comprise a domain or motif with at least one activity of a TFSRP. Moreover, other biologically active portions, in which other regions of the protein are deleted, can be prepared by recombinant techniques and evaluated for one  
25 or more of the activities described herein. Preferably, the biologically active portions of a TFSRP include one or more selected domains/motifs or portions thereof having biological activity.

TFSRPs are preferably produced by recombinant DNA techniques. For example, a nucleic acid molecule encoding the protein is cloned into an expression  
30 vector (as described above), the expression vector is introduced into a host cell (as described above) and the TFSRP is expressed in the host cell. The TFSRP can then be isolated from the cells by an appropriate purification scheme using standard protein purification techniques. Alternative to recombinant expression, a TFSRP, polypeptide,

or peptide can be synthesized chemically using standard peptide synthesis techniques. Moreover, native TFSRP can be isolated from cells (e.g., *Physcomitrella patens*), for example using an anti-TFSRP antibody, which can be produced by standard techniques utilizing a TFSRP or fragment thereof of this invention.

5           The invention also provides TFSRP chimeric or fusion proteins. As used herein, a TFSRP "chimeric protein" or "fusion protein" comprises a TFSRP polypeptide operatively linked to a non-TFSRP polypeptide. An "TFSRP polypeptide" refers to a polypeptide having an amino acid sequence corresponding to a TFSRP, whereas a "non-TFSRP polypeptide" refers to a polypeptide having an amino acid  
10           sequence corresponding to a protein which is not substantially homologous to the TFSRP, e.g., a protein which is different from the TFSRP and which is derived from the same or a different organism. Within the fusion protein, the term "operatively linked" is intended to indicate that the TFSRP polypeptide and the non-TFSRP polypeptide are fused to each other so that both sequences fulfill the proposed function  
15           attributed to the sequence used. The non-TFSRP polypeptide can be fused to the N-terminus or C-terminus of the TFSRP polypeptide. For example, in one embodiment, the fusion protein is a GST-TFSRP fusion protein in which the TFSRP sequences are fused to the C-terminus of the GST sequences. Such fusion proteins can facilitate the purification of recombinant TFSRPs. In another embodiment, the fusion protein is a  
20           TFSRP containing a heterologous signal sequence at its N-terminus. In certain host cells (e.g., mammalian host cells), expression and/or secretion of a TFSRP can be increased through use of a heterologous signal sequence.

          Preferably, a TFSRP chimeric or fusion protein of the invention is produced by standard recombinant DNA techniques. For example, DNA fragments coding for the  
25           different polypeptide sequences are ligated together in-frame in accordance with conventional techniques, for example by employing blunt-ended or stagger-ended termini for ligation, restriction enzyme digestion to provide for appropriate termini, filling-in of cohesive ends as appropriate, alkaline phosphatase treatment to avoid undesirable joining and enzymatic ligation. In another embodiment, the fusion gene  
30           can be synthesized by conventional techniques including automated DNA synthesizers. Alternatively, PCR amplification of gene fragments can be carried out using anchor primers which give rise to complementary overhangs between two consecutive gene fragments which can subsequently be annealed and re-amplified to generate a chimeric

gene sequence (see, for example, *Current Protocols in Molecular Biology*, Eds. Ausubel et al. John Wiley & Sons: 1992). Moreover, many expression vectors are commercially available that already encode a fusion moiety (e.g., a GST polypeptide). A TFSRP-encoding nucleic acid can be cloned into such an expression vector such that the fusion moiety is linked in-frame to the TFSRP.

Homologues of the TFSRP can be generated by mutagenesis, e.g., discrete point mutation or truncation of the TFSRP. As used herein, the term "homologue" refers to a variant form of the TFSRP which acts as an agonist or antagonist of the activity of the TFSRP. An agonist of the TFSRP can retain substantially the same, or a subset, of the biological activities of the TFSRP. An antagonist of the TFSRP can inhibit one or more of the activities of the naturally occurring form of the TFSRP, by, for example, competitively binding to a downstream or upstream member of the cell membrane component metabolic cascade which includes the TFSRP, or by binding to an TFSRP which mediates transport of compounds across such membranes, thereby preventing translocation from taking place.

In an alternative embodiment, homologues of the TFSRP can be identified by screening combinatorial libraries of mutants, e.g., truncation mutants, of the TFSRP for TFSRP agonist or antagonist activity. In one embodiment, a variegated library of TFSRP variants is generated by combinatorial mutagenesis at the nucleic acid level and is encoded by a variegated gene library. A variegated library of TFSRP variants can be produced by, for example, enzymatically ligating a mixture of synthetic oligonucleotides into gene sequences such that a degenerate set of potential TFSRP sequences is expressible as individual polypeptides, or alternatively, as a set of larger fusion proteins (e.g., for phage display) containing the set of TFSRP sequences therein. There are a variety of methods which can be used to produce libraries of potential TFSRP homologues from a degenerate oligonucleotide sequence. Chemical synthesis of a degenerate gene sequence can be performed in an automatic DNA synthesizer, and the synthetic gene is then ligated into an appropriate expression vector. Use of a degenerate set of genes allows for the provision, in one mixture, of all of the sequences encoding the desired set of potential TFSRP sequences. Methods for synthesizing degenerate oligonucleotides are known in the art (see, e.g., Narang, S.A., 1983 *Tetrahedron* 39:3; Itakura et al., 1984 *Annu. Rev. Biochem.* 53:323; Itakura et al., 1984 *Science* 198:1056; Ike et al., 1983 *Nucleic Acid Res.* 11:477).

In addition, libraries of fragments of the TFSRP coding can be used to generate a variegated population of TFSRP fragments for screening and subsequent selection of homologues of a TFSRP. In one embodiment, a library of coding sequence fragments can be generated by treating a double stranded PCR fragment of a TFSRP coding sequence with a nuclease under conditions wherein nicking occurs only about once per molecule, denaturing the double stranded DNA, renaturing the DNA to form double stranded DNA which can include sense/antisense pairs from different nicked products, removing single stranded portions from reformed duplexes by treatment with S1 nuclease, and ligating the resulting fragment library into an expression vector. By this method, an expression library can be derived which encodes N-terminal, C-terminal and internal fragments of various sizes of the TFSRP.

Several techniques are known in the art for screening gene products of combinatorial libraries made by point mutations or truncation, and for screening cDNA libraries for gene products having a selected property. Such techniques are adaptable for rapid screening of the gene libraries generated by the combinatorial mutagenesis of TFSRP homologues. The most widely used techniques, which are amenable to high through-put analysis, for screening large gene libraries typically include cloning the gene library into replicable expression vectors, transforming appropriate cells with the resulting library of vectors, and expressing the combinatorial genes under conditions in which detection of a desired activity facilitates isolation of the vector encoding the gene whose product was detected. Recursive ensemble mutagenesis (REM), a new technique which enhances the frequency of functional mutants in the libraries, can be used in combination with the screening assays to identify TFSRP homologues (Arkin and Yourvan, 1992 PNAS 89:7811-7815; Delgrave et al., 1993 Protein Engineering 6(3):327-331). In another embodiment, cell based assays can be exploited to analyze a variegated TFSRP library, using methods well known in the art. The present invention further provides a method of identifying a novel TFSRP, comprising (a) raising a specific antibody response to a TFSRP, or fragment thereof, as described above; (b) screening putative TFSRP material with the antibody, wherein specific binding of the antibody to the material indicates the presence of a potentially novel TFSRP; and (c) analyzing the bound material in comparison to known TFSRP to determine its novelty.

The nucleic acid molecules, proteins, protein homologues, fusion proteins, primers, vectors, and host cells described herein can be used in one or more of the

following methods: identification of *Physcomitrella patens* and related organisms; mapping of genomes of organisms related to *Physcomitrella patens*; identification and localization of *Physcomitrella patens* sequences of interest; evolutionary studies; determination of TFSRP regions required for function; modulation of an TFSRP  
5 activity; modulation of the metabolism of one or more cell functions; modulation of the transmembrane transport of one or more compounds; and modulation of stress resistance.

The moss *Physcomitrella patens* represents one member of the mosses. It is related to other mosses such as *Ceratodon purpureus* which is capable of growth in the  
10 absence of light. Mosses like *Ceratodon* and *Physcomitrella* share a high degree of homology on the DNA sequence and polypeptide level allowing the use of heterologous screening of DNA molecules with probes evolving from other mosses or organisms, thus enabling the derivation of a consensus sequence suitable for  
heterologous screening or functional annotation and prediction of gene functions in  
15 third species. The ability to identify such functions can therefore have significant relevance, e.g., prediction of substrate specificity of enzymes. Further, these nucleic acid molecules may serve as reference points for the mapping of moss genomes, or of genomes of related organisms.

The TFSRP nucleic acid molecules of the invention have a variety of uses.  
20 Most importantly, the nucleic acid and amino acid sequences of the present invention can be used to transform plants, thereby inducing tolerance to stresses such as drought, high salinity and cold. The present invention therefore provides a transgenic plant transformed by a TFSRP coding nucleic acid, wherein expression of the nucleic acid sequence in the plant results in increased tolerance to environmental stress as  
25 compared to a wild type variety of the plant. The transgenic plant can be a monocot or a dicot. The invention further provides that the transgenic plant can be selected from maize, wheat, rye, oat, triticale, rice, barley, soybean, peanut, cotton, rapeseed, canola, manihot, pepper, sunflower, tagetes, solanaceous plants, potato, tobacco, eggplant, tomato, Vicia species, pea, alfalfa, coffee, cacao, tea, Salix species, oil palm, coconut,  
30 perennial grass and forage crops, for example. In particular, the present invention describes using the expression of CABF-1 (SEQ ID NO:15), DBF-1(SEQ ID NO:16), CBF-1(SEQ ID NO:17), HDZ-1(SEQ ID NO:18), ZF-1(SEQ ID NO:19), LZ-1(SEQ ID NO:20) and CABF-2(SEQ ID NO:21) to engineer drought-tolerant plants. This

strategy has herein been demonstrated for *Arabidopsis thaliana*, Rapeseed/Canola, soybeans, corn and wheat but its application is not restricted to these plants. Accordingly, the invention provides a transgenic plant containing a TFSRP selected from 1) CABF-1; 2) CABF-2; 3) DBF-1; 4) CBF-1; 5) HDZ-1; 6) ZF-1; 7) LZ-1 as defined above, including homologues, wherein the environmental stress is drought. This invention also describes the principle of using over-expression of ZF-1(SEQ ID NO:19), CABF-2(SEQ ID NO:21) and LZ-1(SEQ ID NO:20) to engineer salt-tolerant plants. Again, this strategy has herein been demonstrated for *Arabidopsis thaliana*, Rapeseed/Canola, soybeans, corn and wheat but its application is not restricted to these plants. Accordingly, the invention provides a transgenic plant containing the TFSRP selected from 1) CABF-2; 2) ZF-1; and 3) LZ-1 as defined above, including homologues, wherein the environmental stress is salinity.

The present invention also provides methods of modifying stress tolerance of a plant comprising, modifying the expression of a TFSRP in the plant. The invention provides that this method can be performed such that the stress tolerance is either increased or decreased.

Furthermore, this method can be used wherein the plant is either transgenic or not transgenic. In cases when the plant is transgenic, the plant can be transformed with a vector containing any of the above described TFSRP coding nucleic acids, or the plant can be transformed with a promoter that directs expression of native TFSRP in the plant, for example. The invention provides that such a promoter can be tissue specific. Furthermore, such a promoter can be developmentally regulated. Alternatively, non-transgenic plants can have native TFSRP expression modified by inducing a native promoter. Furthermore, the invention provides that TFSRP expression can be modified by administration of an anti-sense molecule that inhibits expression of TFSRP.

The expression of CABF-1 (SEQ ID NO:15), DBF-1(SEQ ID NO:16), CBF-1(SEQ ID NO:17), HDZ-1(SEQ ID NO:18), ZF-1(SEQ ID NO:19), LZ-1(SEQ ID NO:20) and CABF-2(SEQ ID NO:21) in target plants can be accomplished by, but is not limited to, one of the following examples: (a) constitutive promoter, (b) stress-inducible promoter, (c) chemical-induced promoter, and (d) engineered promoter over-expression with for example zinc-finger derived transcription factors (Greisman and Pabo, 1997 Science 275:657). The later case involves identification of the CABF-1

(SEQ ID NO:15), DBF-1(SEQ ID NO:16), CBF-1(SEQ ID NO:17), HDZ-1(SEQ ID NO:18), ZF-1(SEQ ID NO:19), LZ-1(SEQ ID NO:20) and CABF-2(SEQ ID NO:21) homologues in the target plant as well as from its promoter. Zinc-finger-containing recombinant transcription factors are engineered to specifically interact with the CABF-1 (SEQ ID NO:15), DBF-1(SEQ ID NO:16), CBF-1(SEQ ID NO:17), HDZ-1(SEQ ID NO:18), ZF-1(SEQ ID NO:19), LZ-1(SEQ ID NO:20) and CABF-2(SEQ ID NO:21) homologue and transcription of the corresponding gene is activated.

As shown herein and described more fully below, expression of the TFSRPs (CABF-1 (SEQ ID NO:15), DBF-1(SEQ ID NO:16), CBF-1(SEQ ID NO:17), HDZ-1(SEQ ID NO:18), ZF-1(SEQ ID NO:19), LZ-1(SEQ ID NO:20) and CABF-2 (SEQ ID NO:21)) in *Arabidopsis thaliana* confers a high degree of drought tolerance to the plant. Additionally, several TFSRPs confer tolerance to high salt concentrations (ZF-1(SEQ ID NO:19), LZ-1(SEQ ID NO:20) and CABF-2 (SEQ ID NO:21)) to this plant. Under drought stress conditions, CABF-1 over-expressing lines showed a survival rate of 89%, DBF-1 over-expressing lines showed a survival rate of 80%, CBF-1 over-expressing lines showed a survival rate of 100%; HDZ-1 over-expressing lines showed a survival rate of 50%, ZF-1 over-expressing lines showed a survival rate of 57%, LZ-1 over-expressing lines showed a survival rate of 79%, and CABF-2 over-expressing lines showed a survival rate of 50%. Under salt stress conditions, ZF-1 over-expressing lines showed a survival rate of 52%, CABF-2 over-expressing lines showed a survival rate of 56% and LZ-1 over-expressing lines showed a survival rate of 48%. The untransformed controls showed a survival rate of 10%. It is noteworthy that the analyses of these transgenic lines were performed with T1 plants. Therefore, the results will be better when a homozygous, strong expresser is found. Further proof of involvement of these genes in stress tolerance is given by the increase in the level of transcript in response to cold temperature treatment. The concentration of the transcripts for CABF-1, CABF-2, and CBF-1 are all increased 2 fold over untreated background following the treatment.

In addition to introducing the TFSRP nucleic acid sequences into transgenic plants, these sequences can also be used to identify an organism as being *Physcomitrella patens* or a close relative thereof. Also, they may be used to identify the presence of *Physcomitrella patens* or a relative thereof in a mixed population of microorganisms. The invention provides the nucleic acid sequences of a number of

*Physcomitrella patens* genes; by probing the extracted genomic DNA of a culture of a unique or mixed population of microorganisms under stringent conditions with a probe spanning a region of a *Physcomitrella patens* gene which is unique to this organism, one can ascertain whether this organism is present.

Further, the nucleic acid and protein molecules of the invention may serve as markers for specific regions of the genome. This has utility not only in the mapping of the genome, but also in functional studies of *Physcomitrella patens* proteins. For example, to identify the region of the genome to which a particular *Physcomitrella patens* DNA-binding protein binds, the *Physcomitrella patens* genome could be digested, and the fragments incubated with the DNA-binding protein. Those which bind the protein may be additionally probed with the nucleic acid molecules of the invention, preferably with readily detectable labels; binding of such a nucleic acid molecule to the genome fragment enables the localization of the fragment to the genome map of *Physcomitrella patens*, and, when performed multiple times with different enzymes, facilitates a rapid determination of the nucleic acid sequence to which the protein binds. Further, the nucleic acid molecules of the invention may be sufficiently homologous to the sequences of related species such that these nucleic acid molecules may serve as markers for the construction of a genomic map in related mosses.

The TFSRP nucleic acid molecules of the invention are also useful for evolutionary and protein structural studies. The metabolic and transport processes in which the molecules of the invention participate are utilized by a wide variety of prokaryotic and eukaryotic cells; by comparing the sequences of the nucleic acid molecules of the present invention to those encoding similar enzymes from other organisms, the evolutionary relatedness of the organisms can be assessed. Similarly, such a comparison permits an assessment of which regions of the sequence are conserved and which are not, which may aid in determining those regions of the protein which are essential for the functioning of the enzyme. This type of determination is of value for protein engineering studies and may give an indication of what the protein can tolerate in terms of mutagenesis without losing function.

Manipulation of the TFSRP nucleic acid molecules of the invention may result in the production of TFSRPs having functional differences from the wild-type

TFSRPs. These proteins may be improved in efficiency or activity, may be present in greater numbers in the cell than is usual, or may be decreased in efficiency or activity.

There are a number of mechanisms by which the alteration of a TFSRP of the invention may directly affect stress response and/or stress tolerance. In the case of plants expressing TFSRPs, increased transport can lead to improved salt and/or solute partitioning within the plant tissue and organs. By either increasing the number or the activity of transporter molecules which export ionic molecules from the cell, it may be possible to affect the salt tolerance of the cell.

The effect of the genetic modification in plants, *C. glutamicum*, fungi, algae, or ciliates on stress tolerance can be assessed by growing the modified microorganism or plant under less than suitable conditions and then analyzing the growth characteristics and/or metabolism of the plant. Such analysis techniques are well known to one skilled in the art, and include dry weight, wet weight, protein synthesis, carbohydrate synthesis, lipid synthesis, evapotranspiration rates, general plant and/or crop yield, flowering, reproduction, seed setting, root growth, respiration rates, photosynthesis rates, etc. (Applications of HPLC in Biochemistry in: Laboratory Techniques in Biochemistry and Molecular Biology, vol. 17; Rehm et al., 1993 Biotechnology, vol. 3, Chapter III: Product recovery and purification, page 469-714, VCH: Weinheim; Belter, P.A. et al., 1988 Bioseparations: downstream processing for biotechnology, John Wiley and Sons; Kennedy, J.F. and Cabral, J.M.S., 1992 Recovery processes for biological materials, John Wiley and Sons; Shaeiwitz, J.A. and Henry, J.D., 1988 Biochemical separations, in: Ulmann's Encyclopedia of Industrial Chemistry, vol. B3, Chapter 11, page 1-27, VCH: Weinheim; and Dechow, F.J. (1989) Separation and purification techniques in biotechnology, Noyes Publications).

For example, yeast expression vectors comprising the nucleic acids disclosed herein, or fragments thereof, can be constructed and transformed into *Saccharomyces cerevisiae* using standard protocols. The resulting transgenic cells can then be assayed for fail or alteration of their tolerance to drought, salt, and temperature stress. Similarly, plant expression vectors comprising the nucleic acids disclosed herein, or fragments thereof, can be constructed and transformed into an appropriate plant cell such as *Arabidopsis*, soy, rape, maize, wheat, *Medicago truncatula*, etc., using standard protocols. The resulting transgenic cells and/or plants derived therefrom can

then be assayed for fail or alteration of their tolerance to drought, salt, and temperature stress.

The engineering of one or more TFSRP genes of the invention may also result in TFSRPs having altered activities which indirectly impact the stress response and/or stress tolerance of algae, plants, ciliates or fungi or other microorganisms like *C. glutamicum*. For example, the normal biochemical processes of metabolism result in the production of a variety of products (e.g., hydrogen peroxide and other reactive oxygen species) which may actively interfere with these same metabolic processes (for example, peroxynitrite is known to nitrate tyrosine side chains, thereby inactivating some enzymes having tyrosine in the active site (Groves, J.T., 1999 Curr. Opin. Chem. Biol. 3(2):226-235). While these products are typically excreted, cells can be genetically altered to transport more products than is typical for a wild-type cell. By optimizing the activity of one or more TFSRPs of the invention which are involved in the export of specific molecules, such as salt molecules, it may be possible to improve the stress tolerance of the cell.

Additionally, the sequences disclosed herein, or fragments thereof, can be used to generate knockout mutations in the genomes of various organisms, such as bacteria, mammalian cells, yeast cells, and plant cells. (Girke, T., 1998 The Plant Journal 15:39-48). The resultant knockout cells can then be evaluated for their ability or capacity to tolerate various stress conditions, their response to various stress conditions, and the effect on the phenotype and/or genotype of the mutation. For other methods of gene inactivation include US Patent No. 6004804 "Non-Chimeric Mutational Vectors" and Puttaraju et al., 1999 Spliceosome-mediated RNA *trans*-splicing as a tool for gene therapy Nature Biotechnology 17:246-252.

The aforementioned mutagenesis strategies for TFSRPs to result in increased stress resistance are not meant to be limiting; variations on these strategies will be readily apparent to one skilled in the art. Using such strategies, and incorporating the mechanisms disclosed herein, the nucleic acid and protein molecules of the invention may be utilized to generate algae, ciliates, plants, fungi or other microorganisms like *C. glutamicum* expressing mutated TFSRP nucleic acid and protein molecules such that the stress tolerance is improved.

The present invention also provides antibodies which specifically bind to a TFSRP-polypeptide, or a portion thereof, as encoded by a nucleic acid disclosed herein

or as described herein. Antibodies can be made by many well-known methods (See, e.g. *Harlow and Lane*, "Antibodies; A Laboratory Manual" Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, (1988)). Briefly, purified antigen can be injected into an animal in an amount and in intervals sufficient to elicit an immune response. Antibodies can either be purified directly, or spleen cells can be obtained from the animal. The cells can then fused with an immortal cell line and screened for antibody secretion. The antibodies can be used to screen nucleic acid clone libraries for cells secreting the antigen. Those positive clones can then be sequenced. (See, for example, Kelly et al., 1992 *Bio/Technology* 10:163-167; Bebbington et al., 1992 *Bio/Technology* 10:169-175).

The phrases "selectively binds" and "specifically binds" with the polypeptide refers to a binding reaction which is determinative of the presence of the protein in a heterogeneous population of proteins and other biologics. Thus, under designated immunoassay conditions, the specified antibodies bound to a particular protein do not bind in a significant amount to other proteins present in the sample. Selective binding to an antibody under such conditions may require an antibody that is selected for its specificity for a particular protein. A variety of immunoassay formats may be used to select antibodies selectively bind with a particular protein. For example, solid-phase ELISA immunoassays are routinely used to select antibodies selectively immunoreactive with a protein. See *Harlow and Lane* "Antibodies, A Laboratory Manual" Cold Spring Harbor Publications, New York, (1988), for a description of immunoassay formats and conditions that could be used to determine selective binding.

In some instances, it is desirable to prepare monoclonal antibodies from various hosts. A description of techniques for preparing such monoclonal antibodies may be found in Stites et al., editors, "Basic and Clinical Immunology," (Lange Medical Publications, Los Altos, Calif., Fourth Edition) and references cited therein, and in *Harlow and Lane* ("Antibodies, A Laboratory Manual" Cold Spring Harbor Publications, New York, 1988).

Throughout this application various publications are referenced. The disclosures of all of these publications and those references cited within those publications in their entireties are hereby incorporated by reference into this application in order to more fully describe the state of the art to which this invention pertains.

It should also be understood that the foregoing relates to preferred embodiments of the present invention and that numerous changes may be made therein without departing from the scope of the invention. The invention is further illustrated by the following examples, which are not to be construed in any way as imposing limitations upon the scope thereof. On the contrary, it is to be clearly understood that resort may be had to various other embodiments, modifications, and equivalents thereof, which, after reading the description herein, may suggest themselves to those skilled in the art without departing from the spirit of the present invention and/or the scope of the appended claims. Additionally, all references cited herein are hereby expressly incorporated herein by reference.

## EXAMPLES

### Example 1

#### *Growth of Physcomitrella patens cultures*

For this study, plants of the species *Physcomitrella patens* (Hedw.) B.S.G. from the collection of the genetic studies section of the University of Hamburg were used. They originate from the strain 16/14 collected by H.L.K. Whitehouse in Gransden Wood, Huntingdonshire (England), which was subcultured from a spore by Engel (1968, Am. J. Bot. 55:438-446). Proliferation of the plants was carried out by means of spores and by means of regeneration of the gametophytes. The protonema developed from the haploid spore as a chloroplast-rich chloronema and chloroplast-low caulonema, on which buds formed after approximately 12 days. These grew to give gametophores bearing antheridia and archegonia. After fertilization, the diploid sporophyte with a short seta and the spore capsule resulted, in which the meiospores matured.

Culturing was carried out in a climatic chamber at an air temperature of 25°C and light intensity of 55 micromols<sup>-1</sup>m<sup>2</sup> (white light; Philips TL 65W/25 fluorescent tube) and a light/dark change of 16/8 hours. The moss was either modified in liquid culture using Knop medium according to Reski and Abel (1985, Planta 165:354-358) or cultured on Knop solid medium using 1% oxoid agar (Unipath, Basingstoke, England). The protonemas used for RNA and DNA isolation were cultured in aerated liquid cultures. The protonemas were comminuted every 9 days and transferred to fresh culture medium.

### Example 2

#### *Total DNA isolation from plants*

The details for the isolation of total DNA relate to the working up of one gram fresh weight of plant material. The materials used include the following buffers: CTAB buffer: 2% (w/v) N-cethyl-N,N,N-trimethylammonium bromide (CTAB); 100 mM Tris HCl pH 8.0; 1.4 M NaCl; 20 mM EDTA; N-Laurylsarcosine buffer: 10% (w/v) N-laurylsarcosine; 100 mM Tris HCl pH 8.0; 20 mM EDTA.

The plant material was triturated under liquid nitrogen in a mortar to give a fine powder and transferred to 2 ml Eppendorf vessels. The frozen plant material was then covered with a layer of 1 ml of decomposition buffer (1 ml CTAB buffer, 100  $\mu$ l of N-laurylsarcosine buffer, 20  $\mu$ l of  $\beta$ -mercaptoethanol and 10  $\mu$ l of proteinase K solution, 10 mg/ml) and incubated at 60°C for one hour with continuous shaking. The homogenate obtained was distributed into two Eppendorf vessels (2 ml) and extracted twice by shaking with the same volume of chloroform/isoamyl alcohol (24:1). For phase separation, centrifugation was carried out at 8000 x g and room temperature for 15 minutes in each case. The DNA was then precipitated at -70°C for 30 min using ice-cold isopropanol. The precipitated DNA was sedimented at 4°C and 10,000 g for 30 minutes and resuspended in 180  $\mu$ l of TE buffer (Sambrook et al., 1989, Cold Spring Harbor Laboratory Press: ISBN 0-87969-309-6). For further purification, the DNA was treated with NaCl (1.2 M final concentration) and precipitated again at -70°C for 30 minutes using twice the volume of absolute ethanol. After a washing step with 70% ethanol, the DNA was dried and subsequently taken up in 50  $\mu$ l of H<sub>2</sub>O + RNase (50 mg/ml final concentration). The DNA was dissolved overnight at 4°C and the RNase digestion was subsequently carried out at 37 °C for 1 hour. Storage of the DNA took place at 4°C.

### Example 3

*Isolation of total RNA and poly-(A)+ RNA and cDNA library construction from Physcomitrella patens*

For the investigation of transcripts, both total RNA and poly-(A)<sup>+</sup> RNA were isolated. The total RNA was obtained from wild-type 9 day old protonemata following the GTC-method (Reski et al., 1994 Mol. Gen. Genet. 244:352-359). The Poly(A)<sup>+</sup> RNA was isolated using Dyna Beads<sup>®</sup> (Dyna, Oslo, Norway) following the instructions of the manufacturers protocol. After determination of the concentration of the RNA or of the poly(A)<sup>+</sup> RNA, the RNA was precipitated by addition of 1/10 volumes of 3 M sodium acetate pH 4.6 and 2 volumes of ethanol and stored at -70°C.

For cDNA library construction, first strand synthesis was achieved using Murine Leukemia Virus reverse transcriptase (Roche, Mannheim, Germany) and oligo-d(T)-primers, second strand synthesis by incubation with DNA polymerase I, Klenow

enzyme and RNaseH digestion at 12°C (2 hours), 16°C (1 hour) and 22°C (1 hour). The reaction was stopped by incubation at 65°C (10 minutes) and subsequently transferred to ice. Double stranded DNA molecules were blunted by T4-DNA-polymerase (Roche, Mannheim) at 37°C (30 minutes). Nucleotides were removed by phenol/chloroform extraction and Sephadex G50 spin columns. EcoRI adapters (Pharmacia, Freiburg, Germany) were ligated to the cDNA ends by T4-DNA-ligase (Roche, 12°C, overnight) and phosphorylated by incubation with polynucleotide kinase (Roche, 37°C, 30 minutes). This mixture was subjected to separation on a low melting agarose gel. DNA molecules larger than 300 base pairs were eluted from the gel, phenol extracted, concentrated on Elutip-D-columns (Schleicher and Schuell, Dassel, Germany) and were ligated to vector arms and packed into lambda ZAPII phages or lambda ZAP-Express phages using the Gigapack Gold Kit (Stratagene, Amsterdam, Netherlands) using material and following the instructions of the manufacturer.

#### Example 4

##### *Sequencing and function annotation of Physcomitrella patens ESTs*

cDNA libraries as described in Example 2 were used for DNA sequencing according to standard methods, and in particular, by the chain termination method using the ABI PRISM Big Dye Terminator Cycle Sequencing Ready Reaction Kit (Perkin-Elmer, Weiterstadt, Germany). Random Sequencing was carried out subsequent to preparative plasmid recovery from cDNA libraries via *in vivo* mass excision, retransformation, and subsequent plating of DH10B on agar plates (material and protocol details from Stratagene, Amsterdam, Netherlands. Plasmid DNA was prepared from overnight grown *E. coli* cultures grown in Luria-Broth medium containing ampicillin (see Sambrook et al. 1989 Cold Spring Harbor Laboratory Press: ISBN 0-87969-309-6) on a Qiagen DNA preparation robot (Qiagen, Hilden) according to the manufacturer's protocols. Sequencing primers with the following nucleotide sequences were used:

5'-CAGGAAACAGCTATGACC-3'	SEQ ID NO:24
5'-CTAAAGGGAACAAAAGCTG-3'	SEQ ID NO:25
5'-TGTAACACGACGGCCAGT-3'	SEQ ID NO:26

Sequences were processed and annotated using the software package EST-MAX commercially provided by Bio-Max (Munich, Germany). The program incorporates practically all bioinformatics methods important for functional and structural characterization of protein sequences. For reference the website at

### Example 5

*Identification of Physcomitrella patens ORF corresponding to CABF-1, DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2*

The *Physcomitrella patens* partial cDNAs (ESTs) shown in Table 1 below were identified in the *Physcomitrella patens* EST sequencing program using the program EST-MAX through BLAST analysis. (Tables 2-8 show some of these results). The Sequence Identification Numbers corresponding to these ESTs are as follows: CABF-1 (SEQ ID NO:1), DBF-1 (SEQ ID NO:2), CBF-1 (SEQ ID NO:3), HDZ-1 (SEQ ID NO:4), ZF-1 (SEQ ID NO:5), LZ-1 (SEQ ID NO:6) and CABF-2 (SEQ ID NO:7)

These particular clones were chosen for further analyses since they encoded for transcription factors.

**Example 6**

*Cloning of the full-length Physcomitrella patens cDNA encoding for CABF-1, DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1, CABF-2*

- 5 To isolate full-length CABF-1 (SEQ ID NO:8), CABF-2 (SEQ ID NO:14), CBF-1 (SEQ ID NO:10), PCR was performed as described below under the title "Full-length Amplification" using the original ESTs described in Example 4 as template since they were full-length (see Table 9 for primers).

Table 9  
Scheme and primers used for cloning of full-length clones

Gene	Final sites in product	Isolation Method	Primers Race	Primer RT-PCR
DBF-1	XmaI/HpaI	5' RACE and RT-PCR for Full-length clone	RC056 (SEQ ID NO:27) 5'GCGATCCTCAGC CTGTCGATCCATT3'  RC116 (SEQ ID NO:28) 5'CCCTGAGGTATC GTTCTGGTTCCTCA 3'	RC279 (SEQ ID NO:29) 5'ATCCCGGGGCGAT GGTGCGTTCGAGAT CGTAAGG3'  RC280 (SEQ ID NO:30) 5'GCGTTAAGGAGC TTTCTCGCAGTGCC AGATAA3'

To isolate the clones encoding for DBF-1 (SEQ ID NO:9), HDZ-1 (SEQ ID NO:11), ZF-1 (SEQ ID NO:12) and LZ-1 (SEQ ID NO:13) from *Physcomitrella patens*, cDNA libraries were created with SMART RACE cDNA Amplification kit (Clontech Laboratories) following manufacturer's instructions. Total RNA isolated as described in Example 2 was used as the template. The cultures were treated prior to RNA isolation as follows: Salt Stress: 2, 6, 12, 24, 48 hours with 1-M NaCl-supplemented medium; Cold Stress: 4°C for the same time points as for salt; Drought Stress: cultures were incubated on dry filter paper for the same time points above. RNA was then pulled and used for isolation.

#### 5' RACE Protocol

The EST sequences DBF-1 (SEQ ID NO:2), HDZ-1 (SEQ ID NO:4), ZF-1 (SEQ ID NO:5) and LZ-1 (SEQ ID NO:6) identified from the database search as described in Example 4 were used to design oligos for RACE (see Table 9). The extended sequences for these genes were obtained by performing Rapid Amplification of cDNA Ends polymerase chain reaction (RACE PCR) using the Advantage 2 PCR kit (Clontech Laboratories) and the SMART RACE cDNA amplification kit (Clontech

Laboratories) using a Biometra T3 Thermocycler following the manufacturer's instructions. The sequences obtained from the RACE reactions corresponded to full-length coding regions of HDZ-1, ZF-1 and LZ-1 and were used to design oligos for full-length cloning of the respective genes (see below full-length amplification). The RACE product of DBF-1 was not full length and a new RACE reaction was needed (see Table 9 for primers).

#### Full-length Amplification

Full-length clones corresponding CABF-1 (SEQ ID NO:8), CBF-1 (SEQ ID NO:10) and CABF-2 (SEQ ID NO:14) were obtained by performing polymerase chain reaction (PCR) with gene-specific primers (see Table 9) and the original EST as the template. The conditions for the reaction were standard conditions with PWO DNA polymerase (Roche). PCR was performed according to standard conditions and to manufacturer's protocols (Sambrook et al., 1989 Molecular Cloning, A Laboratory Manual. 2nd Edition. Cold Spring Harbor Laboratory Press. Cold Spring Harbor, N.Y., Biometra T3 Thermocycler). The parameters for the reaction were: five minutes at 94°C followed by five cycles of one minute at 94°C, one minute at 50°C and 1.5 minutes at 72°C. This was followed by twenty five cycles of one minute at 94°C, one minute at 65°C and 1.5 minutes at 72°C.

Full-length clones corresponding to the DBF-1 (SEQ ID NO:9), HDZ-1 (SEQ ID NO:11), ZF-1 (SEQ ID NO:12) and LZ-1 (SEQ ID NO:13) genes were isolated by repeating the RACE method but using the gene-specific primers as given in Table 9.

The amplified fragments were extracted from agarose gel with a QIAquick Gel Extraction Kit (Qiagen) and ligated into the TOPO pCR 2.1 vector (Invitrogen) following manufacturer's instructions. Recombinant vectors were transformed into Top10 cells (Invitrogen) using standard conditions (Sambrook et al. 1989. Molecular Cloning, A Laboratory Manual. 2nd Edition. Cold Spring Harbor Laboratory Press. Cold Spring Harbor, NY). Transformed cells were selected for on LB agar containing 100 µg/ml carbenicillin, 0.8 mg X-gal (5-bromo-4-chloro-3-indolyl-β-D-galactoside) and 0.8 mg IPTG (isopropylthio-β-D-galactoside) grown overnight at 37°C. White colonies were selected and used to inoculate 3 ml of liquid LB containing 100 µg/ml ampicillin and grown overnight at 37°C. Plasmid DNA was extracted using the QIAprep Spin Miniprep Kit (Qiagen) following manufacturer's instructions. Analyses of subsequent clones and restriction mapping was performed according to standard molecular biology techniques (Sambrook et al., 1989 Molecular Cloning, A Laboratory Manual. 2nd Edition. Cold Spring Harbor Laboratory Press. Cold Spring Harbor, N.Y.).

**Example 7**

*Engineering stress-tolerant Arabidopsis plants by over-expressing the genes CABF-1, DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2*

Binary vector construction: pGMSG

5 The pLMNC53 (Mankin, 2000, PhD thesis) vector was digested with HindIII (Roche) and blunt-end filled with Klenow enzyme and 0.1 mM dNTPs (Roche) according to manufacturer's instructions. This fragment was extracted from agarose gel with a QIAquick Gel Extraction Kit (Qiagen) according to manufacturer's instructions. The purified fragment was then digested with EcoRI (Roche) according to  
10 manufacturer's instructions. This fragment was extracted from agarose gel with a QIAquick Gel Extraction Kit (Qiagen) according to manufacturer's instructions. The resulting 1.4 kilobase fragment, the gentamycin cassette, included the nos promoter, aacCI gene and the g7 terminator.

The vector pBlueScript was digested with EcoRI and SmaI (Roche) according  
15 to manufacturer's instructions. The resulting fragment was extracted from agarose gel with a QIAquick Gel Extraction Kit (Qiagen) according to manufacturer's instructions. The digested pBlueScript vector and the gentamycin cassette fragments were ligated with T4 DNA Ligase (Roche) according to manufacturer's instructions, joining the two  
20 respective EcoRI sites and joining the blunt-ended HindIII site with the SmaI site.

The recombinant vector (pGMBS) was transformed into Top10 cells (Invitrogen) using standard conditions. Transformed cells were selected for on LB agar containing 100 µg/ml carbenicillin, 0.8 mg X-gal (5-bromo-4-chloro-3-indolyl-β-D-galactoside) and 0.8 mg IPTG (isopropylthio-β-D-galactoside), grown overnight at 37°C. White colonies were selected and used to inoculate 3 ml of liquid LB containing  
25 100 µg/ml ampicillin and grown overnight at 37°C. Plasmid DNA was extracted using the QIAprep Spin Miniprep Kit (Qiagen) following manufacturer's instructions. Analyses of subsequent clones and restriction mapping was performed according to standard molecular biology techniques (Sambrook et al. 1989. Molecular Cloning. A Laboratory Manual. 2nd Edition. Cold Spring Harbor Laboratory Press. Cold Spring  
30 Harbor, N.Y.).

Both the pGMBS vector and p1bxSuperGUS vector were digested with XbaI and KpnI (Roche) according to manufacturer's instructions, excising the gentamycin cassette from pGMBS and producing the backbone from the p1bxSuperGUS vector. The resulting fragments were extracted from agarose gel with a QIAquick Gel  
35 Extraction Kit (Qiagen) according to manufacturer's instructions. These two fragments were ligated with T4 DNA ligase (Roche) according to manufacturer's instructions.

The resulting recombinant vector (pGMSG) was transformed into Top10 cells (Invitrogen) using standard conditions. Transformed cells were selected for on LB agar containing 100 µg/ml carbenicillin, 0.8 mg X-gal (5-bromo-4-chloro-3-indolyl-β-D-galactoside) and 0.8 mg IPTG (isopropylthio-β-D-galactoside) and grown overnight at 37°C. White colonies were selected and used to inoculate 3 ml of liquid LB containing 100 µg/ml ampicillin and grown overnight at 37°C. Plasmid DNA was extracted using the QIAprep Spin Miniprep Kit (Qiagen) following manufacturer's instructions. Analyses of subsequent clones and restriction mapping was performed according to standard molecular biology techniques (Sambrook et al., 1989 Molecular Cloning, A Laboratory Manual, 2nd Edition. Cold Spring Harbor Laboratory Press. Cold Spring Harbor, NY).

Subcloning of CABF-1, DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2 into the binary vector

The fragments containing the different *Physcomitrella patens* transcription factors were subcloned from the recombinant PCR2.1 TOPO vectors by double digestion with restriction enzymes (see Table 10) according to manufacturer's instructions. The subsequence fragment was excised from agarose gel with a QIAquick Gel Extraction Kit (QIAGEN) according to manufacturer's instructions and ligated into the binary vector pGMSG, cleaved with appropriate enzymes (see Table 10) and dephosphorylated prior to ligation. The resulting recombinant pGMSG vector contained the corresponding transcription factor in the sense orientation under the control of the constitutive super promoter.

Table 10

Names of the various constructs of the *Physcomitrella patens* transcription factors used for plant transformation

Gene	Enzymes used to generate gene fragment	Enzymes used to restrict pGMSG	Binary Vector Construct
CABF-1	XmaI/SacI	XmaI/SacI	pBPSSH003
DBF-1	XmaI/HpaI	XmaI/Ecl136	pBPPLVLM009
CBF-1	XmaI/HpaI	XmaI/Ecl136	pBPSSH002
HDZ-1	XmaI/HpaI	XmaI/Ecl136	pBPPLVLM007
ZF-1	XmaI/SacI	XmaI/SacI	pBPPLVLM008
LZ-1	HpaI/EcoRV	Ecl136	pBPPLVLM012
CABF-2	XmaI/SacI	XmaI/SacI	pBPPLM003

### Agrobacterium Transformation

The recombinant vectors were transformed into *Agrobacterium tumefaciens* C58C1 and PMP90 according to standard conditions (Hoefgen and Willmitzer, 1990).

### Plant Transformation

*Arabidopsis thaliana* ecotype C24 were grown and transformed according to standard conditions (Bechtold, 1993 Acad. Sci. Paris. 316:1194-1199; Bent et al., 1994 Science 265:1856-1860).

### Screening of Transformed Plants

T1 seeds were sterilized according to standard protocols (Xiong et al. 1999, Plant Molecular Biology Reporter 17: 159-170). Seeds were plated on ½ MS 0.6% agar supplemented with 1% sucrose, 150 µg/ml gentamycin (Sigma-Aldrich) and 2 µg/ml benomyl (Sigma-Aldrich). Seeds on plates were vernalized for four days at 4°C. The seeds were germinated in a climatic chamber at an air temperature of 22°C and light intensity of 40 micromols<sup>-1</sup>m<sup>2</sup> (white light; Philips TL 65W/25 fluorescent tube) and 16 hours light and 8 hours dark day length cycle. Transformed seedlings were selected after 14 days and transferred to ½ MS 0.6% agar plates supplemented with 1% sucrose and allowed to recover for five-seven days.

### Drought Tolerance Screening

T1 seedlings were transferred to dry, sterile filter paper in a petri dish and allowed to desiccate for two hours at 80% RH (relative humidity) in a Sanyo Growth Cabinet MLR-350H, micromols<sup>-1</sup>m<sup>2</sup> (white light; Philips TL 65W/25 fluorescent tube). The RH was then decreased to 60% and the seedlings were desiccated further for eight hours. Seedlings were then removed and placed on ½ MS 0.6% agar plates supplemented with 2 µg/ml benomyl and scored after five days.

The results of the drought tolerance screening in *Arabidopsis thaliana* plants over-expressing the TFSRP are shown in Table 11. It is noteworthy that these analyses were performed with T1 plants since the results should be better when a homozygous, strong expresser is found.

Table 11  
Summary of the drought stress tests

Gene Name	Drought Stress Test		
	Number of survivors	Total number of plants	Percentage of survivors
HDZ-1	7	14	50%
ZF-1	25	45	53%
CABF-1	8	9	89%
DBF-1	4	5	80%
CABF-2	3	6	50%
LZ-1	11	14	79%
CBF-1	9	9	100%
Control	18	84	21%

#### 5 Salt Tolerance Screening

Seedlings were transferred to filter paper soaked in  $\frac{1}{2}$  MS and placed on  $\frac{1}{2}$  MS 0.6% agar supplemented with 2  $\mu\text{g/ml}$  benomyl the night before the salt tolerance screening. For the salt tolerance screening, the filter paper with the seedlings was moved to stacks of sterile filter paper, soaked in 50 mM NaCl, in a petri dish. After two hours, the filter paper with the seedlings was moved to stacks of sterile filter paper, soaked with 200 mM NaCl, in a petri dish. After two hours, the filter paper with the seedlings was moved to stacks of sterile filter paper, soaked in 600mM NaCl, in a petri dish. After 10 hours, the seedlings were moved to petri dishes containing  $\frac{1}{2}$  MS 0.6% agar supplemented with 2  $\mu\text{g/ml}$  benomyl. The seedlings were scored after 5 days.

The results of the salt tolerance screening in *Arabidopsis thaliana* plants over-expressing the TFSRPs are shown in Table 12. In particular, ZF-1 over-expressing *Arabidopsis thaliana* plants showed a 52% (12 survivors from 23 stressed plants) survival rate; LZ-1, 48% (10 survivor from 21 stressed plants); CABF-2, 56% (5 survivors from 9 stressed plants); whereas the untransformed control a 9% (2 survivors from 23 tested plants) survival rate. It is noteworthy that these analyses were performed with T1 plants, and therefore, the results should be better when a homozygous, strong expresser is found.

Table 12  
Summary of the salt stress tests

Gene Name	Salt Stress Test		
	Number of survivors	Total number of plants	Percentage of survivors
ZF-1	12	23	52%
CABF-2	5	9	56%
LZ-1	10	21	48%
Control	2	23	9%

#### Freezing Tolerance Screening

Seedlings were moved to petri dishes containing  $\frac{1}{2}$  MS 0.6% agar supplemented with 2% sucrose and 2  $\mu$ g/ml benomyl. After four days, the seedlings were incubated at 4°C for 1 hour and then covered with shaved ice. The seedlings were then placed in an Environmental Specialist ES2000 Environmental Chamber and incubated for 3.5 hours beginning at -1.0°C decreasing -1°C hour. The seedlings were then incubated at -5.0°C for 24 hours and then allowed to thaw at 5°C for 12 hours. The water was poured off and the seedlings were scored after 5 days. The transgenic plants are then screened for their improved cold tolerance demonstrating that transgene expression confers cold tolerance.

#### Example 8

*Detection of the CABF-1, DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1, and CABF-2 transgenes in the transgenic Arabidopsis lines*

One leaf from a wild type and a transgenic *Arabidopsis* plant was homogenized in 250  $\mu$ l Hexadecyltrimethyl ammonium bromide (CTAB) buffer (2% CTAB, 1.4 M NaCl, 8mM EDTA and 20mM Tris pH 8.0) and 1  $\mu$ l  $\beta$ -mercaptoethanol. The samples were incubated at 60-65°C for 30 minutes and 250  $\mu$ l of Chloroform was then added to each sample. The samples were vortexed for 3 minutes and centrifuged for 5 minutes at 18,000 x g. The supernatant was taken from each sample and 150  $\mu$ l isopropanol was added. The samples were incubated at room temperature for 15 minutes, and centrifuged for 10 minutes at 18,000 x g. Each pellet was washed with 70% ethanol, dried, and resuspended in 20  $\mu$ l TE. 4  $\mu$ l of above suspension was used in a 20  $\mu$ l PCR reaction using *Taq* DNA polymerase (Roche Molecular Biochemicals) according to the manufacturer's instructions. Binary vector plasmid containing each TFSRP gene was used as positive control, and the wild type C24 genomic DNA was used as negative

control in the PCR reactions. 10 µl PCR reaction was analyzed on 0.8% agarose - ethidium bromide gel.

The primers and reaction times used for amplification of each TFSRP gene are below. Notably, the transgenes were successfully amplified from the T1 transgenic lines, but not from the wild type C24. This result indicates that the T1 transgenic plants contain at least one copy of the transgenes. There was no indication of the existence of either identical or very similar genes in the untransformed *Arabidopsis thaliana* control which could be amplified by this method.

#### CABF-1

The primers used in the reactions were:

5'GAATAGATACGCTGACACGC3' SEQ ID NO:46

5'ATGAGCTCACTCTTACACTCCGGGGGTGGTT3' SEQ ID NO:47

The PCR program was: 1 cycle of 1 minute at 94°C, 1 minute at 75°C and 3 minutes at 72°C, followed by 14 cycles of the same cycle except that the annealing temperature decreased 1°C every cycle until 62°C; and then 16 cycles of 1 minute at 94°C, 1 minute at 62°C and 3 minutes at 72°C. A 600-base pair fragment was generated from the positive control and the transgenic plants.

#### HDZ-1

The primers used in the reactions were:

5'GAATAGATACGCTGACACGC3' SEQ ID NO:46

5'GCGTTAACGCCGATGGTGCAACTTGGTTGAC3' SEQ ID NO:48

The PCR program was as following: 30 cycles of 1 minute at 94°C, 1 minute at 62°C and 4 minutes at 72°C, followed by 10 minutes at 72°C. A 1.3-kb fragment was produced from the positive control and the transgenic plants.

#### ZF-1

The primers used in the reactions were:

5'GAATAGATACGCTGACACGC3' SEQ ID NO:46

5'GCGAGCTCGACCTTGCTCGATGGAGACTCCAAT3' SEQ ID NO:49

The PCR program was as following: 1 cycle of 1 minute at 94°C, 1 minute at 75°C and 3 minutes at 72°C, followed by 14 cycles of the same cycle except that the annealing temperature decreased 1 °C every cycle until 62°C; and then 16 cycles of 1 minute at 94°C, 1 minute at 62°C and 3 minutes at 72°C. A 1.3-kb fragment was generated from the positive control and the T1 transgenic plants.

#### CBF-1

The primers used in the reactions were:

5'GAATAGATACGCTGACACGC3' SEQ ID NO:46

5'GCGTTAACGACTCACTGAGAGTCATAATGGTG3' SEQ ID NO:50

The PCR program was as following: 1 cycle of 1 minute at 94°C, 1 minute at 75°C and 3 minutes at 72°C, followed by 14 cycles of the same cycle except that the annealing temperature decreased 1°C every cycle until 62°C; and then 16 cycles of 1 minute at 94°C, 1 minute at 62°C and 3 minutes at 72°C. A 1.1-kb fragment was generated from the positive control and the T1 transgenic plants.

#### DBF-1

The primers used in the reactions were:

5'CTAGTAACATAGATGACACC3' SEQ ID NO:51

5'ATCCCGGCGATGGTTCGATCGTAAGG3' SEQ ID NO:52

The PCR program was as following: 30 cycles of 1 minute at 94°C, 1 minute at 62°C and 4 minutes at 72°C, followed by 10 minutes at 72°C. A 2.9-kb fragment was produced from the positive control and the transgenic plants.

#### CABF-2

The primers used in the reactions were:

5'GAATAGATACGCTGACACGC3' SEQ ID NO:53

5'CTGAGCTCTAATGCATTCACTGTTGCTGCTGCT3' SEQ ID NO:54

The PCR program was as following: 30 cycles of 1 minute at 94°C, 1 minute at 62°C and 4 minutes at 72°C, followed by 10 minutes at 72°C. An 800-bp fragment was produced from the positive control and the transgenic plants.

#### LZ-1

The primers used in the reactions were:

5'GAATAGATACGCTGACACGC3' SEQ ID NO:55

5'GCGATATCGCTTCCATACCTGCGCCGAAGACTT3' SEQ ID NO:56

The PCR program was as following: 30 cycles of 1 minute at 94°C, 1 minute at 62°C and 4 minutes at 72°C, followed by 10 minutes at 72°C. A 1.8-kb fragment was produced from the positive control and the transgenic plants.

### **Example 9**

*Detection of the CABF-1, DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1, and CABF-2 transgene mRNA in transgenic Arabidopsis lines*

Transgene expression was detected using RT-PCR. Total RNA was isolated from stress-treated plants using a procedure adapted from (Verwoerd et al., 1989 NAR 17:2362). Leaf samples (50-100 mg) were collected and ground to a fine powder in liquid nitrogen. Ground tissue was resuspended in 500 µl of an 80°C, 1:1 mixture, of phenol to extraction buffer (100mM LiCl, 100 mM Tris pH8, 10 mM EDTA, 1% SDS), followed by brief vortexing to mix. After the addition of 250 µl of chloroform,

each sample was vortexed briefly. Samples were then centrifuged for 5 minutes at 12,000 x g. The upper aqueous phase was removed to a fresh eppendorf tube. RNA was precipitated by adding 1/10<sup>th</sup> volume 3M sodium acetate and 2 volumes 95% ethanol. Samples were mixed by inversion and placed on ice for 30 minutes. RNA was pelleted by centrifugation at 12,000 x g for 10 minutes. The supernatant was removed and pellets briefly air-dried. RNA sample pellets were resuspended in 10 µl DEPC treated water. To remove contaminating DNA from the samples, each was treated with RNase-free DNase (Roche) according to the manufacturer's recommendations. cDNA was synthesized from total RNA using the 1<sup>st</sup> Strand cDNA synthesis kit (Boehringer Mannheim) following manufacturer's recommendations. PCR amplification of a gene-specific fragment from the synthesized cDNA was performed using Taq DNA polymerase (Roche) and gene-specific primers (see Table 13 for primers) in the following reaction: 1X PCR buffer, 1.5 mM MgCl<sub>2</sub>, 0.2 µM each primer, 0.2 µM dNTPs, 1 unit polymerase, 5 µl cDNA from synthesis reaction. Amplification was performed under the following conditions: Denaturation, 95°C, 1 minute; annealing, 62°C, 30 seconds; extension, 72°C, 1 minute, 35 cycles; extension, 72°C, 5 minutes; hold, 4°C, forever. PCR products were run on a 1% agarose gel, stained with ethidium bromide, and visualized under UV light using the Quantity-One gel documentation system (Bio-Rad).

Expression of the transgenes was detected in the T1 transgenic line. These results indicated that the transgenes are expressed in the transgenic lines and strongly suggested that their gene product improved plant stress tolerance in the transgenic lines. In agreement with the previous statement, no expression of identical or very similar endogenous genes could be detected by this method. These results are in agreement with the data from Example 7.

Table 13

Primers used for the amplification of respective transgene mRNA in PCR using RNA isolated from transgenic *Arabidopsis thaliana* plants as template

Gene	5' primer	3' primer

### Example 10

*Engineering stress-tolerant soybean plants by over-expressing the CABF-1; DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2 gene*

- 5 The constructs pBPSLVM111, pBPSLVM149, pBPSLVM157, pBPSLVM39, pBPSLVM12, pBPSLVM19, pBPSLVM69 were used to transform soybean as described below.

- 10 Seeds of soybean were surface sterilized with 70% ethanol for 4 minutes at room temperature with continuous shaking, followed by 20% (v/v) Clorox supplemented with 0.05% (v/v) Tween for 20 minutes with continuous shaking. Then, the seeds were rinsed 4 times with distilled water and placed on moistened sterile filter paper in a Petri dish at room temperature for 6 to 39 hours. The seed coats were peeled

off, and cotyledons are detached from the embryo axis. The embryo axis was examined to make sure that the meristematic region is not damaged. The excised embryo axes were collected in a half-open sterile Petri dish and air-dried to a moisture content less than 20% (fresh weight) in a sealed Petri dish until further use.

5 *Agrobacterium tumefaciens* culture was prepared from a single colony in LB solid medium plus appropriate antibiotics (e.g. 100 mg/l streptomycin, 50 mg/l kanamycin) followed by growth of the single colony in liquid LB medium to an optical density at 600 nm of 0.8. Then, the bacteria culture was pelleted at 7000 rpm for 7 minutes at room temperature, and resuspended in MS (Murashige and Skoog, 1962) medium supplemented with 100  $\mu$ M acetosyringone. Bacteria cultures were incubated in this pre-induction medium for 2 hours at room temperature before use. The axis of soybean zygotic seed embryos at approximately 15% moisture content were imbibed for 2 hours at room temperature with the pre-induced *Agrobacterium* suspension culture. The embryos are removed from the imbibition culture and were transferred to 15 Petri dishes containing solid MS medium supplemented with 2% sucrose and incubated for 2 days, in the dark at room temperature. Alternatively, the embryos were placed on top of moistened (liquid MS medium) sterile filter paper in a Petri dish and incubated under the same conditions described above. After this period, the embryos were transferred to either solid or liquid MS medium supplemented with 500 mg/L 20 carbenicillin or 300mg/L cefotaxime to kill the agrobacteria. The liquid medium was used to moisten the sterile filter paper. The embryos were incubated during 4 weeks at 25°C, under 150  $\mu$ mol m<sup>-2</sup>sec<sup>-1</sup> and 12 hours photoperiod. Once the seedlings produced roots, they were transferred to sterile metromix soil. The medium of the *in vitro* plants was washed off before transferring the plants to soil. The plants were kept under a 25 plastic cover for 1 week to favor the acclimatization process. Then the plants were 25 transferred to a growth room where they were incubated at 25°C, under 150  $\mu$ mol m<sup>-2</sup>sec<sup>-1</sup> light intensity and 12 hours photoperiod for about 80 days.

The transgenic plants were then screened for their improved drought, salt and/or cold tolerance according to the screening method described in Example 7 30 demonstrating that transgene expression confers stress tolerance.

#### Example 11

*Engineering stress-tolerant Rapeseed/Canola plants by over-expressing the CABF-1; DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2 gene*

35 The constructs pBPSLVM111, pBPSLVM149, pBPSLVM157, pBPSLVM39, pBPSLVM12, pBPSLVM19, pBPSLVM69 were used to transform rapeseed/canola as described below.

The method of plant transformation described herein is also applicable to Brassica and other crops. Seeds of canola are surface sterilized with 70% ethanol for 4 minutes at room temperature with continuous shaking, followed by 20% (v/v) Clorox supplemented with 0.05 % (v/v) Tween for 20 minutes, at room temperature with continuous shaking. Then, the seeds are rinsed 4 times with distilled water and placed on moistened sterile filter paper in a Petri dish at room temperature for 18 hours. Then the seed coats are removed and the seeds are air dried overnight in a half-open sterile Petri dish. During this period, the seeds lose approx. 85% of its water content. The seeds are then stored at room temperature in a sealed Petri dish until further use. DNA constructs and embryo imbibition are as described in Example 10. Samples of the primary transgenic plants (T0) are analyzed by PCR to confirm the presence of T-DNA. These results are confirmed by Southern hybridization in which DNA is electrophoresed on a 1% agarose gel and transferred to a positively charged nylon membrane (Roche Diagnostics). The PCR DIG Probe Synthesis Kit (Roche Diagnostics) is used to prepare a digoxigenin-labelled probe by PCR, and used as recommended by the manufacturer.

The transgenic plants are then screened for their improved stress tolerance according to the screening method described in Example 7 demonstrating that transgene expression confers drought tolerance.

#### Example 12

*Engineering stress-tolerant corn plants by over-expressing the CABF-1; DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2 gene*

The constructs pBPSLVM111, pBPSLVM149, pBPSLVM157, pBPSLVM39, pBPSLVM12, pBPSLVM19, pBPSLVM69 were used to transform corn as described below.

Transformation of maize (*Zea Mays L.*) is performed with the method described by Ishida et al., 1996 Nature Biotech 14745-50. Immature embryos are co-cultivated with *Agrobacterium tumefaciens* that carry "super binary" vectors, and transgenic plants are recovered through organogenesis. This procedure provides a transformation efficiency of between 2.5% and 20%. The transgenic plants are then screened for their improved drought, salt and/or cold tolerance according to the screening method described in Example 7 demonstrating that transgene expression confers stress tolerance.

**Example 13**

*Engineering stress-tolerant wheat plants by over-expressing the CABF-1; DBF-1, CBF-1, HDZ-1, ZF-1, LZ-1 and CABF-2 gene*

The constructs pBPSLVM111, pBPSLVM149, pBPSLVM157, pBPSLVM39, pBPSLVM12, pBPSLVM19, pBPSLVM69 were used to transform wheat as described below.

Transformation of wheat is performed with the method described by Ishida et al. 1996. Nature Biotech 14745-50. Immature embryos are co-cultivated with *Agrobacterium tumefaciens* that carry "super binary" vectors, and transgenic plants are recovered through organogenesis. This procedure provides a transformation efficiency between 2.5% and 20%. The transgenic plants are then screened for their improved stress tolerance according to the screening method described in Example 7 demonstrating that transgene expression confers drought tolerance.

**Example 14**

*Monitoring changes in mRNA concentration of CABF-1, CABF-2 and CBF-1 in Physcomitrella patens cultures cold treated*

**DNA Microarray slide preparation**

PCR amplification was performed in 96 well plates from selected *Physcomitrella patens* ESTs cloned in the pBluescript vector. The PCR buffer set (Boehringer Mannheim) was employed for PCR reaction. Each PCR reaction mixture contains 10 µl of PCR Buffer without MgCl<sub>2</sub>, 10 µl of MgSO<sub>4</sub>, 3 µl of SK-Fwd primer (MWG-Biotech, Sequence: 5'-CGCCAAGCGCGCAATTAACCTCACT-3', SEQ ID NO:76), 3 µl SK-Rev primer (MWG-Biotech, Sequence: 5'-GCGTAATACGACTCACTATAGGG CGA-3', SEQ ID NO:77), 2 µl dNTP, 1 µl Taq DNA polymerase (Roche), 72 µl water and 1 µl DNA template. After denaturing at 95°C for three minutes, the PCR reactions were performed with 35 cycles of three consecutive steps including denaturing at 95°C for 45 seconds, annealing at 63°C for 45 seconds, and elongation at 72°C for 60 seconds. The last elongation was 72°C for 10 minutes. The PCR products were then purified with QIAquick PCR purification kit (Qiagen, Inc.), eluted with water and the DNA concentration measured at 260 nm in a spectrophotometer.

2 to 5 µg of each PCR product were dried down and dissolved in 50 µl of DMSO. The PCR products were then formatted from 96 well plates to 384 well plates for printing. Microarray GenIII arrayer (Molecular Dynamics) was employed to print the PCR products to microarray slides (Molecular Dynamics) with the format recommended by the manufacturer. The printed spots were about 290 µm in diameter

and were spaced about 320  $\mu\text{m}$  from center to center. After printing, the slide was left in the dust free chamber for one hour to dry out. UV cross-link was performed with 600  $\mu\text{J}/\text{mm}$ . The cross-linked slides were ready for hybridization and were stored in dark and dry chambers.

#### Microarray probe synthesis

Total RNA was extracted from cold-treated *Physcomitrella patens* cultures (12 hours at 4°C in the dark) following the RNA extraction method described in Ausubel et al. (1987 Curr. Prot. in Mol. Biol. J. Wiley and Sons, New York). Oligotex mRNA midi kit (Qiagen Inc.) was applied to isolate mRNA from total RNA with an approach combining both batch and standard protocol recommended by the manufacturer. After binding the total RNA with Oligotex, the sample was centrifuged at 14000 x g to separate the Oligotex:mRNA with the liquid phase instead of running through a column. After four washes with OW2 buffer as described in batch protocol, the Oligotex:mRNA was resuspended in 400  $\mu\text{l}$  OW2 and then collected by the column as the standard protocol. The mRNA was eluted following standard protocol.

Cy3 and Cy5 labeled cDNA probes were synthesized from mRNA with Superscript Choice System for cDNA synthesis (Gibco BRL). Both oligo-(dT)<sub>25</sub> primer (Genosys Biotechnologies) and Nonamer primer (Amersham Pharmacia Biotech) were mixed with mRNA to reach a total volume of 20  $\mu\text{l}$ . The mixture was first heated at 70°C for 10 minutes and then left at room temperature for 15 minutes before transferring to ice. Once the sample is on ice, add 8  $\mu\text{l}$  First Strand Synthesis Buffer, 4  $\mu\text{l}$  0.1M DTT, 2  $\mu\text{l}$  dNTP (Amersham Pharmacia Biotech), 2  $\mu\text{l}$  Cy3- or Cy5- dCTP (Amersham Pharmacia Biotech), 2  $\mu\text{l}$  RNase Inhibitor (Gibco BRL) and 2  $\mu\text{l}$  SuperScript II Reverse Transcriptase. The first strand synthesis was performed at 42°C for 8 hours and the mixture was then heated at 94°C for three minutes after the reaction.

After the first strand synthesis, 4  $\mu\text{l}$  of 2.5M sodium hydroxide was added to the reaction and the mixture was incubated at 37°C for ten minutes. 20  $\mu\text{l}$  of 2M MOPS (pH 5.0) and 500  $\mu\text{l}$  of PB buffer (Qiagen Inc.) were then added to each reaction. The probe was then purified by the QIAquick PCR Purification Kit (Qiagen Inc.) with the protocol provided by the manufacturer.

#### cDNA Microarray hybridization and washes

The purified Cy3- and Cy5- labeled probes were mixed and vacuum dried to give a final volume of 9  $\mu\text{l}$ . 9  $\mu\text{l}$  Microarray Hybridization Solution (Amersham Pharmacia Biotech) and 18  $\mu\text{l}$  Formamide (Sigma) were then added to the cDNA probes to give a final volume of 36  $\mu\text{l}$ . The mixture was applied to the printed

microarray slide that was then covered with a clean dust-free cover slide with no air trapped. The hybridization was performed in a hybridization chamber at 42°C for 16 to 20 hours. After the hybridization, the slides were washed two times with 0.5XSSC, 0.2%SDS at room temperature for 5 minutes and 15 minutes. Two times of stringent washes were performed with 0.25XSSC, 0.1% SDS at 55°C for 10 and 30 minutes respectively. After the washes, the slides were briefly rinsed with Millipore water and dried under compressed nitrogen.

#### Scanning, Microarray data analysis

The cDNA microarrays were scanned using the microarray GenIII Scanner (Molecular Dynamics) equipped with two laser channels. The scanned images were firstly viewed and adjusted in ImageQuant software (Molecular Dynamics) and then analyzed by ArrayVision software (Molecular Dynamics). The signal intensity for each spot was extracted by ArrayVision software (Molecular Dynamics) and transferred to Excel (Microsoft). The data obtained was normalized by dividing the difference of the intensity value and background and the difference of the control value and background. The ratio was then obtained by dividing the normalized data.

### **Example 15**

#### *Identification of Homologous and Heterologous Genes*

Gene sequences can be used to identify homologous or heterologous genes from cDNA or genomic libraries. Homologous genes (e. g. full-length cDNA clones) can be isolated via nucleic acid hybridization using for example cDNA libraries. Depending on the abundance of the gene of interest, 100,000 up to 1,000,000 recombinant bacteriophages are plated and transferred to nylon membranes. After denaturation with alkali, DNA is immobilized on the membrane by e.g. UV cross linking. Hybridization is carried out at high stringency conditions. In aqueous solution hybridization and washing is performed at an ionic strength of 1 M NaCl and a temperature of 68°C. Hybridization probes are generated by e. g. radioactive (<sup>32</sup>P) nick transcription labeling (High Prime, Roche, Mannheim, Germany). Signals are detected by autoradiography.

Partially homologous or heterologous genes that are related but not identical can be identified in a manner analogous to the above-described procedure using low stringency hybridization and washing conditions. For aqueous hybridization, the ionic strength is normally kept at 1 M NaCl while the temperature is progressively lowered from 68 to 42°C.

Isolation of gene sequences with homologies (or sequence identity/similarity) only in a distinct domain of (for example 10-20 amino acids) can be carried out by

using synthetic radio labeled oligonucleotide probes. Radio labeled oligonucleotides are prepared by phosphorylation of the 5-prime end of two complementary oligonucleotides with T4 polynucleotide kinase. The complementary oligonucleotides are annealed and ligated to form concatemers. The double stranded concatemers are than radiolabeled by, for example, nick transcription. Hybridization is normally performed at low stringency conditions using high oligonucleotide concentrations.

Oligonucleotide hybridization solution:

6 x SSC

0.01 M sodium phosphate

1 mM EDTA (pH 8)

0.5 % SDS

100 µg/ml denatured salmon sperm DNA

0.1 % nonfat dried milk

During hybridization, temperature is lowered stepwise to 5-10°C below the estimated oligonucleotide  $T_m$  or down to room temperature followed by washing steps and autoradiography. Washing is performed with low stringency such as 3 washing steps using 4 x SSC. Further details are described by Sambrook, J. et al., 1989, "Molecular Cloning: A Laboratory Manual", Cold Spring Harbor Laboratory Press or Ausubel, F.M. et al., 1994 "Current Protocols in Molecular Biology", John Wiley & Sons.

### Example 16

#### *Identification of Homologous Genes by Screening Expression Libraries with Antibodies*

c-DNA clones can be used to produce recombinant protein for example in E. coli (e. g. Qiagen QIAexpress pQE system). Recombinant proteins are then normally affinity purified via Ni-NTA affinity chromatography (Qiagen). Recombinant proteins are then used to produce specific antibodies for example by using standard techniques for rabbit immunization. Antibodies are affinity purified using a Ni-NTA column saturated with the recombinant antigen as described by Gu et al., 1994 BioTechniques 17:257-262. The antibody can then be used to screen expression cDNA libraries to identify homologous or heterologous genes via an immunological screening (Sambrook, J. et al., 1989, "Molecular Cloning: A Laboratory Manual", Cold Spring Harbor Laboratory Press or Ausubel, F.M. et al., 1994 "Current Protocols in Molecular Biology", John Wiley & Sons).

**Example 17***In vivo Mutagenesis*

*In vivo* mutagenesis of microorganisms can be performed by passage of plasmid (or other vector) DNA through *E. coli* or other microorganisms (e.g. *Bacillus* spp. or yeasts such as *Saccharomyces cerevisiae*) which are impaired in their capabilities to maintain the integrity of their genetic information. Typical mutator strains have mutations in the genes for the DNA repair system (e.g., mutHLS, mutD, mutT, etc.; for reference, see Rupp, W.D., 1996 DNA repair mechanisms, in: *Escherichia coli* and *Salmonella*, p. 2277-2294, ASM: Washington.) Such strains are well known to those skilled in the art. The use of such strains is illustrated, for example, in Greener, A. and Callahan, M., 1994 Strategies 7:32-34. Transfer of mutated DNA molecules into plants is preferably done after selection and testing in microorganisms. Transgenic plants are generated according to various examples within the exemplification of this document.

**Example 18***In vitro Analysis of the Function of Physcomitrella Genes in Transgenic Organisms*

The determination of activities and kinetic parameters of enzymes is well established in the art. Experiments to determine the activity of any given altered enzyme must be tailored to the specific activity of the wild-type enzyme, which is well within the ability of one skilled in the art. Overviews about enzymes in general, as well as specific details concerning structure, kinetics, principles, methods, applications and examples for the determination of many enzyme activities may be found, for example, in the following references: Dixon, M., and Webb, E.C., (1979) *Enzymes*. Longmans: London; Fersht, (1985) *Enzyme Structure and Mechanism*. Freeman: New York; Walsh, (1979) *Enzymatic Reaction Mechanisms*. Freeman: San Francisco; Price, N.C., Stevens, L. (1982) *Fundamentals of Enzymology*. Oxford Univ. Press: Oxford; Boyer, P.D., ed. (1983) *The Enzymes*, 3<sup>rd</sup> ed. Academic Press: New York; Bisswanger, H., (1994) *Enzymkinetik*, 2<sup>nd</sup> ed. VCH: Weinheim (ISBN 3527300325); Bergmeyer, H.U., Bergmeyer, J., Graßl, M., eds. (1983-1986) *Methods of Enzymatic Analysis*, 3<sup>rd</sup> ed., vol. I-XII, Verlag Chemie: Weinheim; and Ullmann's Encyclopedia of Industrial Chemistry (1987) vol. A9, *Enzymes*. VCH: Weinheim, p. 352-363.

The activity of proteins which bind to DNA can be measured by several well-established methods, such as DNA band-shift assays (also called gel retardation assays). The effect of such proteins on the expression of other molecules can be measured using reporter gene assays (such as that described in Kolmar, H. et al., 1995 EMBO J. 14:3895-3904 and references cited therein). Reporter gene test systems are

well known and established for applications in both pro- and eukaryotic cells, using enzymes such as  $\beta$ -galactosidase, green fluorescent protein, and several others.

The determination of activity of membrane-transport proteins can be performed according to techniques such as those described in Gennis, R.B. Pores, Channels and Transporters, in Biomembranes, Molecular Structure and Function, pp. 85-137, 199-234 and 270-322, Springer: Heidelberg (1989).

#### Example 19

##### *Purification of the Desired Product from Transformed Organisms*

Recovery of the desired product from plant material (i.e., *Physcomitrella patens* or *Arabidopsis thaliana*), fungi, algae, ciliates, *C. glutamicum* cells, or other bacterial cells transformed with the nucleic acid sequences described herein, or the supernatant of the above-described cultures can be performed by various methods well known in the art. If the desired product is not secreted from the cells, can be harvested from the culture by low-speed centrifugation, the cells can be lysed by standard techniques, such as mechanical force or sonification. Organs of plants can be separated mechanically from other tissue or organs. Following homogenization cellular debris is removed by centrifugation, and the supernatant fraction containing the soluble proteins is retained for further purification of the desired compound. If the product is secreted from desired cells, then the cells are removed from the culture by low-speed centrifugation, and the supernate fraction is retained for further purification.

The supernatant fraction from either purification method is subjected to chromatography with a suitable resin, in which the desired molecule is either retained on a chromatography resin while many of the impurities in the sample are not, or where the impurities are retained by the resin while the sample is not. Such chromatography steps may be repeated as necessary, using the same or different chromatography resins. One skilled in the art would be well-versed in the selection of appropriate chromatography resins and in their most efficacious application for a particular molecule to be purified. The purified product may be concentrated by filtration or ultrafiltration, and stored at a temperature at which the stability of the product is maximized.

There is a wide array of purification methods known to the art and the preceding method of purification is not meant to be limiting. Such purification techniques are described, for example, in Bailey, J.E. & Ollis, D.F. Biochemical Engineering Fundamentals, McGraw-Hill: New York (1986). Additionally, the identity and purity of the isolated compounds may be assessed by techniques standard in the art. These include high-performance liquid chromatography (HPLC), spectroscopic

methods, staining methods, thin layer chromatography, NIRS, enzymatic assay, or microbiologically. Such analysis methods are reviewed in: Patek et al., 1994 Appl. Environ. Microbiol. 60:133-140; Malakhova et al., 1996 Biotekhnologiya 11:27-32; and Schmidt et al., 1998 *Bioprocess Engineer.* 19:67-70. Ulmann's Encyclopedia of Industrial Chemistry, (1996) vol. A27, VCH: Weinheim, p. 89-90, p. 521-540, p. 540-547, p. 559-566, 575-581 and p. 581-587; Michal, G. (1999) Biochemical Pathways: An Atlas of Biochemistry and Molecular Biology, John Wiley and Sons; Fallon, A. et al. (1987) Applications of HPLC in Biochemistry in: Laboratory Techniques in Biochemistry and Molecular Biology, vol. 17.

## CLAIMS

WE CLAIM:

1. A transgenic plant transformed by a transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein expression of the nucleic acid sequence in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant.

2. The transgenic plant of Claim 1, wherein the TFSRP is selected from 1) CAAT-Box like Binding Factor (CABF); 2) DNA Binding Factor (DBF); 3) Homeo Domain/Leucine Zipper (HDZ); 4) Zinc-Finger Factor (ZF); and 5) Leucine Zipper (LZ).

3. The transgenic plant of Claim 1, wherein the TFSRP is selected from 1) CAAT-Box like Binding Factor-1 (CABF-1) as defined in SEQ ID NO:15; 2) CAAT-Box like Binding Factor-2 (CABF-2) as defined in SEQ ID NO:21; 3) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:16; 4) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:23; 5) CRT/DRE Binding Factor-1 (CBF-1) as defined in SEQ ID NO:17; 6) Homeo Domain/Leucine Zipper-1 (HDZ-1) as defined in SEQ ID NO:18; 7) Zinc-Finger Factor-1 (ZF-1) as defined in SEQ ID NO:19; 8) Leucine Zipper-1 (LZ-1) as defined in SEQ ID NO:20; and homologues thereof.

4. The transgenic plant of Claim 1, wherein the TFSRP coding nucleic acid is selected from 1) CAAT-Box like Binding Factor-1 (CABF-1) as defined in SEQ ID NO:8; 2) CAAT-Box like Binding Factor-2 (CABF-2) as defined in SEQ ID NO:14; 3) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:9; 4) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:22; 5) CRT/DRE Binding Factor-1 (CBF-1) as defined in SEQ ID NO:10; 6) Homeo Domain/Leucine Zipper-1 (HDZ-1) as defined in SEQ ID NO:11; 7) Zinc-Finger Factor-1 (ZF-1) as defined in SEQ ID NO:12; 8) Leucine Zipper-1 (LZ-1) as defined in SEQ ID NO:13; and homologues thereof.

5. The transgenic plant of any of Claims 3 or 4, wherein the nucleic acid and protein are from a *Physcomitrella patens*.

6. The transgenic plant of Claim 1, wherein the TFSRP is selected from 1) CAAT-Box like Binding Factor-1 (CABF-1) as defined in SEQ ID NO:15; 2)

CAAT-Box like Binding Factor-2 (CABF-2) as defined in SEQ ID NO:21; 3) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:16; 4) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:23; 5) CRT/DRE Binding Factor-1 (CBF-1) as defined in SEQ ID NO:17; 6) Homeo Domain/Leucine Zipper-1 (HDZ-1) as defined in SEQ ID NO:18; 7) Zinc-Finger Factor-1 (ZF-1) as defined in SEQ ID NO:19; 8) Leucine Zipper-1 (LZ-1) as defined in SEQ ID NO:20.

7. The transgenic plant of Claim 1, wherein the TFSRP coding nucleic acid is selected from 1) CAAT-Box like Binding Factor-1 (CABF-1) as defined in SEQ ID NO:8; 2) CAAT-Box like Binding Factor-2 (CABF-2) as defined in SEQ ID NO:14; 3) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:9; 4) DNA Binding Factor-1 (DBF-1) as defined in SEQ ID NO:22; 5) CRT/DRE Binding Factor-1 (CBF-1) as defined in SEQ ID NO:10; 6) Homeo Domain/Leucine Zipper-1 (HDZ-1) as defined in SEQ ID NO:11; 7) Zinc-Finger Factor-1 (ZF-1) as defined in SEQ ID NO:12; 8) Leucine Zipper-1 (LZ-1) as defined in SEQ ID NO:13.

8. The transgenic plant of Claim 1, wherein the environmental stress is selected from salinity, drought, and temperature.

9. A transgenic plant of any of Claims 2, 3, 5 and 6, wherein the environmental stress is salinity, and the TFSRP is selected from 1) CABF-2; 2) ZF-1; and 3) LZ-1.

10. A transgenic plant of any of Claims 4, 5 and 7, wherein the environmental stress is salinity, and the TFSRP coding nucleic acid is selected from 1) CABF-2; 2) ZF-1; and 3) LZ-1.

11. A transgenic plant of any of Claims 2, 3, 5 and 6, wherein the environmental stress is drought, and the TFSRP is selected from 1) CABF-1; 2) CABF-2; 3) DBF-1; 4) CBF-1; 5) HDZ-1; 6) ZF-1; and 7) LZ-1.

12. A transgenic plant of any of Claims 4, 5 and 7, wherein the environmental stress is drought, and the TFSRP coding nucleic acid is selected from 1) CABF-1; 2) CABF-2; 3) DBF-1; 4) CBF-1; 5) HDZ-1; 6) ZF-1; and 7) LZ-1.

13. The transgenic plant of any of Claims 1-12, wherein the plant is a monocot.
- 5 14. The transgenic plant of any of Claims 1-12, wherein the plant is a dicot.
15. The transgenic plant of any of Claims 1-12, wherein the plant is selected from maize, wheat, rye, oat, triticale, rice, barley, soybean, peanut, cotton, rapeseed, canola, manihot, pepper, sunflower, tagetes, solanaceous plants, potato, tobacco, eggplant, tomato, Vicia species, pea, alfalfa, coffee, cacao, tea, Salix species, oil palm, coconut, perennial grass and forage crops.
- 10 16. A seed produced by a transgenic plant transformed by a transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein the seed contains the TFSRP of any of Claims 2, 3, 5, 6, 8, 9 and 11, and wherein the plant is true breeding for increased tolerance to environmental stress as compared to a wild type variety of the plant.
- 15 17. A seed produced by a transgenic plant transformed by a transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein the seed contains the TFSRP coding nucleic acid of any of Claims 4, 5, 7, 8, 10 and 12, and wherein the plant is true breeding for increased tolerance to environmental stress as compared to a wild type variety of the plant.
- 20 18. An agricultural product produced by the plant or seed of any of claims 1-17.
- 25 19. An isolated transcription factor stress-related protein (TFSRP), wherein the TFSRP is as described in any of Claims 2, 3, 5, 6, 8, 9 and 11.
- 30 20. An isolated transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein the TFSRP coding nucleic acid codes for a TFSRP as described in any of Claims 2, 3, 5, 6, 8, 9 and 11.
- 35 21. An isolated transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein the TFSRP coding nucleic acid is as described in any of Claims 4, 5, 7, 8, 10 and 12.

22. An isolated recombinant expression vector comprising a nucleic acid of any of Claims 20 and 21, wherein expression of the vector in a host cell results in increased tolerance to environmental stress as compared to a wild type variety of the host cell.

23. A host cell containing the vector of Claim 22.

24. The host cell of Claim 23, wherein the cell is in a plant.

25. A method of producing a transgenic plant with a transcription factor stress-related protein (TFSRP) coding nucleic acid, wherein expression of the nucleic acid in the plant results in increased tolerance to environmental stress as compared to a wild type variety of the plant comprising,

(a) transforming a plant cell with an expression vector comprising the TFSRP coding nucleic acid, and

(b) generating from the plant cell a transgenic plant with an increased tolerance to environmental stress as compared to a wild type variety of the plant.

26. The method of Claim 25, wherein the TFSRP is as described in any of Claims 2, 3, 5, 6, 8, 9 and 11.

27. The method of Claim 25, wherein the TFSRP coding nucleic acid is as described in any of Claims 4, 5, 7, 8, 10 and 12.

28. A method of increasing expression of a gene of interest within a host cell as compared to a wild type variety of the host cell, wherein the gene of interest is transcribed in response to a transcription factor stress-related protein (TFSRP), comprising,

(a) transforming the host cell with an expression vector comprising a TFSRP coding nucleic acid, and

(b) expressing the TFSRP within the host cell, thereby increasing the expression of the gene transcribed in response to the TFSRP as compared to a wild type variety of the host cell.

29. The method of Claim 28, wherein the TFSRP is as described in any of Claims 2, 3, 5, 6, 8, 9 and 11.

30. The method of Claim 28, wherein the TFSRP coding nucleic acid is as described in any of Claims 4, 5, 7, 8, 10 and 12.

31. A method of identifying a novel transcription factor stress-related protein (TFSRP) comprising,

(a) raising a specific antibody response to a TFSRP as described in any of Claims 2, 3, 5, 6, 8, 9 and 11;

(b) screening putative TFSRP material with the antibody, wherein specific binding of the antibody to the material indicates the presence of a potentially novel TFSRP; and

(c) identifying the bound material as a novel TFSRP.

32. A method of modifying stress tolerance of a plant comprising, modifying the expression of a transcription factor stress-related protein (TFSRP) in the plant, wherein the TFSRP is as described in any of Claims 2, 3, 5, 6, 8, 9 and 11.

33. The method of Claim 32, wherein the stress tolerance is increased.

34. The method of Claim 32, wherein the stress tolerance is decreased.

35. The method of Claim 32, wherein the plant is not transgenic.

36. The method of Claim 32, wherein the plant is transgenic.

37. The method of Claim 36, wherein the plant is transformed with TFSRP coding nucleic acid as described in any of Claims 4, 5, 7, 8, 10 and 12.

38. The method of Claim 36, wherein the plant is transformed with a promoter that directs expression of native TFSRP.

39. The method of Claim 38, wherein the promoter is tissue specific.

40. The method of Claim 38, wherein the promoter is developmentally regulated.

5 41. The method of Claim 32, wherein TFSRP expression is modified by administration of an anti-sense molecule that inhibits expression of TFSRP.
